> The American Council on Education, representing higher education in this country, has carefully evaluated the content and quality of the many courses given in both these categories. It has issued the "Guide to the Evaluation of Educational Experiences in the Armed Forces" to assist colleges desiring to do so to award proper high school and college credit for specific courses taken in this program.
>
> B. In addition to awarding credit for courses actually taken, as described in A, there is a program for evaluating a veteran's knowledge in a given field by administering "General Educational Development Tests" and awarding appropriate credit at the high school and college levels on the basis of the examination results, even though formal course work in the subject matter of the examination was not taken by the candidate. These are comprehensive examinations developed by the Armed Forces Institute and sponsored by the American Council on Education.
>
> C. The Council on Medical Education and Hospitals of the American Medical Association (*a*) has confidence in the American Council on Education and its "Guide to the Evaluation of Educational Experiences in the Armed Forces," in the Armed Forces Institute and in the General Educational Development tests and (*b*) wishes to support sound procedures permitting veterans to commence their education in civilian institutions at a level commensurate with their ability and knowledge. Therefore the Council has decided that approved medical schools desiring to accept students at the freshman level partially on the basis of high school or college awarded credit as described in A and B will not be in conflict with the Council's regulations and policies, except that college credit for science courses requiring laboratory work should not be allowed on this basis, nor should blanket credit be allowed for military service not based on courses or examinations. Specifically, a medical college may accept, in partial fulfilment of premedical requirements:
>
> 1. High school credits, based on
>
> (*a*) Courses taken from the Armed Forces Institute or in service courses of the armed forces according to the "Guide to the Evaluation of Educational Experiences in the Armed Forces."
>
> (*b*) Performance in the General Educational Development Tests; such credit may include the equivalent of a complete high school course.
>
> 2. College credits (except in science courses requiring laboratory work, or except blanket credits for military services not based on courses or examinations), based on
>
> (*a*) Courses taken from the Armed Forces Institute or in service courses of the armed forces according to the "Guide to the Evaluation of Educational Experiences in the Armed Forces."
>
> (*b*) Performance in the General Education Development Tests.

The licensing boards of all but four states have indicated that the awarding of premedical credits under this plan by approved medical schools as the equivalent of the required premedical training will satisfy the requirement for licensure.

The Army Specialized Training and Navy V-12 premedical programs called for less than two years of college training, but in both these programs the studies were continuous and provided for the student carrying more than the normal peacetime studies per semester. Both the Army and Navy programs provided for work well in excess of the sixty semester hours constituting the normal two academic years of medical study. The information received from those states whose licensure laws include specific premedical requirements seems to indicate that there should be no licensure difficulties encountered by students whose premedical work was taken under the Army Specialized Training or Navy V-12 or comparably accelerated civilian programs.

† Some states require the internship from graduates of medical faculties abroad and from reciprocity or endorsement applicants.

* Internship must be rotating service.

REQUIRED INTERNSHIPS

The medical schools requiring an internship for the M.D. degree are shown in table 16. There are six schools in the United States and four in Canada with this requirement. There has been no change in this list in the past three years. In the academic year 1945-1946 there were 488 students of schools in the United States and 156 from Canadian schools, a total of 644, engaged in the required year of internship training or research.

Although relatively few schools require the internship for the M.D. degree, this is a requirement for licensure by twenty-three state medical licensing boards, the District of Columbia, Alaska, the Canal Zone, Hawaii Puerto Rico and the Virgin Islands (table 17). These states have returned to the prewar requirement of a one year internship but will continue to accept the nine month wartime internship. Table 18 lists these states and indicates the relationship of their requirement to the former nine month internship. Eight states, the Connecticut homeopathic examining board, Alaska, the Canal Zone, Hawaii and Puerto Rico will accept the nine month internship as fulfilling the internship requirement. Eleven states and the District of Columbia require an additional three months in a civilian hospital or military service but will permit applicants for licensure to write the examination but withhold the license until this is completed. In four states and the Virgin Islands medical officers will be required to show completion of a year's internship, three months of which may be in military service.

The licensing boards of Delaware, Hawaii, Illinois, Iowa, Michigan, New Jersey, North Dakota, Pennsylvania, Rhode Island, Utah, Washington and Wisconsin require the internship to be a rotating service.

A few of the medical schools and licensing boards maintain their own list of hospitals acceptable for intern training, but the list of approved internships compiled by the Council on Medical Education and Hospitals of the American Medical Association is generally used.

TABLE 18.—*Relationship of the Former Nine Month Internship to Licensure*

	Additional Three Months in Civilian Hospital or Military Service Required	
Accepted as Fulfilling Internship Requirement	Will Give Examination at End of Nine Months	Will Not Give Examination Until Completion of Year's Service
Alaska	Alabama [1]	Illinois [2]
Canal Zone	Delaware	New Mexico
Connecticut (homeo. board)	Dist of Columbia [1]	Utah
Hawaii [3]	Iowa [1]	*Virgin Islands*

Nevada	South Dakota [1,2]	
New Hampshire	Vermont	
New Jersey	Washington [1]	
Oklahoma [1]	Wisconsin	
Pennsylvania	Wyoming	
Puerto Rico [2]		

1. Will also give examination on completion of the medical course but withhold license until internship is completed.
2. Military medical service must be in a military hospital.
3. License issued after year's residence.

LICENSURE FOR MEDICAL OFFICERS

In February 1946[3] the Federation of State Medical Boards published a statement based on a canvass of respective licensing boards of the country on several points pertaining to the licensure of returning medical officers. The text of this report indicates that medical officers will be required to satisfy peacetime licensure regulations except in a few instances where special consideration is given to such applications. However, in several ways the medical licensing boards have attempted to be of assistance to medical officers in returning to the private practice of medicine, i. e. the issuance of temporary permits, relaxation of the one year internship requirement and the licensure of physicians by reciprocity and endorsement of credentials. At present there is only one state—Florida—which requires a written examination of all applicants for medical licensure. Reciprocity meetings have been held at more frequent intervals than previously. The advantage of this procedure is evidenced by the fact that in 1946 there were 9,570 so licensed as compared with 3,615 licensed in 1945.

The medical practice acts of most states, by opinion of the attorney general in several instances, do not provide for the acceptance of government credentials as a basis for licensure without examination. The boards of four states may issue a license without examination to a physician who has passed an examination for admission to the medical corps of the U. S. Army, Navy or Public Health Service. These states are California, Illinois, Utah and Virginia. Act No. 132, approved April 25, 1945, provides for the licensure of legal residents of Pennsylvania who were qualified in every respect to take the state board examinations in Pennsylvania but were prevented from doing so by reason of enlistment or induction into the military or naval forces of the United States in World War II. In South Dakota former medical officers of World War II are exempted by law from the basic science board examination. In Wisconsin honorably discharged officers of the government services may be licensed without examination. New York and Ohio will admit graduates of unapproved medical schools to its examinations under certain conditions.

The Bureau of Information of the American Medical Association is continuing to help veteran medical officers with their medical practice and relocation problems. This is done through close association with state and county medical societies as an entirely voluntary effort without any attempt to direct the location of a physician.

An officer can obtain a brief but comprehensive picture of the economic status of any particular area he is interested in from the data contained on county summary sheets. This includes data on population, principal cities, physicians' hospital and medical facilities and pertinent economic, social and financial information. A copy of this summary sheet is forwarded to the inquirer, and a copy of the letter to him is sent to the state and county medical society concerned.

In addition to the information contained on the summary sheets, other data are available for interested officers. Requests for full or part time salaried medical positions from industries, institutions and other organizations, requests from practicing physicians for associates, needs for specialists and requests of individuals for practices are cross filed and kept current by a return post card system which keeps the Bureau of Information informed of final locations, filling of vacancies and the securing of physicians.

At its December 1945 meeting the Council on Medical Education and Hospitals of the American Medical Association passed the following resolution:

> The Council on Medical Education and Hospitals of the American Medical Association does not intend to remove any hospital from the lists of hospitals approved for internships or residencies which furnishes teaching facilities to any veteran medical officer who is eligible for educational benefits under the Servicemen's Readjustment Act, provided the veteran is legally eligible for medical licensure in the state in which the hospital is located.

This action of the Council was approved by the Federation of State Medical Boards at its meeting on Feb. 12, 1946. The American College of Surgeons is also in accord with this policy of the Council on Medical Education and Hospitals.

TEMPORARY PERMITS

The licensing boards of thirteen states, Alaska and Puerto Rico provide for the issuance of temporary permits. These states, the length of validity of the permit and the number of permits granted during the last calendar year are shown in table 19. Nevada, North Dakota and Pennsylvania discontinued this emergency regulation in 1946, while Nebraska was added to the list. There were 809 temporary permits granted during the year as compared with 323 in 1945.

1. Reciprocity applicants.
2. Discontinued Jan. 1, 1947.
3. Medical officers of World War II.

ANNUAL REGISTRATION

Thirty states, the District of Columbia, Alaska and Hawaii require physicians to register their licenses annually. In table 20 are listed the licensing boards which have such a requirement and the fee charged. Some of these boards require such registration whether or not physicians reside in the states.

CANDIDATES EXAMINED, 1942-1946

In table 21 are tabulated the numbers of candidates examined in the various states, territories and possessions in the five year period from 1942 to 1946 inclusive. For each year there is recorded the number who passed and failed licensing examinations. Totals for the five year period and the percentage of candidates who failed are also given.

During this five year period 35,976 examinations were given: 31,811 were successful tests and 4,165 (11.6 per cent) failures. New York leads in the number of examinations given. In this state in the last five years 2,878 passed the licensure examination. More than 2,000 also were successful in California, Illinois and Pennsylvania. More than 1,000 were examined in seven other states and passed, namely Louisiana, Maryland, Michigan, Minnesota, Missouri, Ohio and Texas.

TABLE 20.—*States Requiring Annual Registration*

	Fee		Fee		Fee
Alaska	$10	Idaho	$2	New York *	$4
Arizona	3	Indiana	5[c]	North Dakota	[e]

Hawaii	2	New Mexico	..	Wyoming	2.50

a. Residents $2, nonresidents $4.
b. Residents $2, nonresidents $10.
c. Effective July 1, 1947.
d. Residents $5, nonresidents $1.
e. Residents $5, nonresidents $2.
* Biennial registration

The highest percentage of failures (57.9) occurred in Massachusetts. This high percentage is due to the fact that, by law, the licensing board admitted to its examinations the graduates of unapproved medical schools and graduates of osteopathic schools, many of whom repeatedly fail. A recent amendment to the medical practice act established a State Approving Authority. This body has ruled that students matriculated in institutions not meeting the standards of the Authority after Jan. 1, 1941 will not be eligible to take the licensing examination.

Percentage Failed	15.3		10.9		11.9		9.9		9.9		11.6		

New York had a failure percentage of 42.2, occasioned in large part by the admittance to examination of a considerable number of graduates of foreign medical schools, who likewise repeatedly fail in large numbers. The number of such graduates admitted to licensure has been decreasing in the last few years. However, the recent regulation admitting certain graduates of unapproved medical schools to its licensure examination resulted in a high percentage of failures in 1946. Other high failure percentages occurred in Connecticut, Nevada and New Hampshire. On the other hand, thirty-seven states failed less than 5 per cent in the five year period. These included nine states which had no failures: Alabama, Arkansas, Kansas, New Mexico, Oklahoma, South Dakota, Utah, West Virginia and Wyoming. The percentage of failures in all states has decreased from 15.3 in 1942 to 9.9 in 1946. The lowest percentage of failures in this five year period occurred in 1945 and 1946, when 9.9 per cent failed.

These figures represent examinations given and not individuals examined. A candidate who fails more than once in a state in a given year is counted only once, but should he also fail in a succeeding year he is counted in that year also. The same is true of successful candidates who migrate to other states. This group represents a recapitulation of the statistics computed annually and assembled for comparative purposes. It gives only a fair approximation of the number of physicians added to the profession in five years by the written examination method. Table 12, page 271, gives the corrected compilation of the number of physicians representing additions to the medical profession.

TABLE 22.—*Registration of Physicians, 1904-1946*

Year	Examined	Passed	Percentage Failed	Reciprocity or Endorsement	Total Registered

1946	7,605	6,853	9.9	9,570	16,423

REGISTRATION, 1904-1946

A tabulation of totals and percentages for forty-three years (1904-1946) is included in table 22. This compilation covers physicians registered by written examination and by reciprocity or endorsement of credentials. There is no definite trend in the numbers annually registered from 1904 to 1933, although in 1918 the number registered dropped to the all time low record of 4,231. After 1933 there was an upward trend for a time, followed by a decline during the years 1941 and 1942. The decline of more than 1,200 in 1918 was due to the sudden withdrawal of physicians and recent graduates from civilian life during World War I. By contrast in 1943 the number registered increased 1,239 over the preceding year. The increase is a result of the accelerated curriculum and the universal effort on the part of the medical leaders of the country to maintain a steady flow of physicians for both civilian and military practice. In 1943 more physicians were examined than in any previous year. A large majority of these were recent graduates who secured licenses before assuming military duties.

The number registered in 1946 was almost twice as many as were registered in 1945. Separation from service of a large number of medical officers and their return to private practice in states other than those in which they were licensed accounts in large part for this increase.

The percentage of failures gradually dropped from 19.3 in 1904, when a great many proprietary medical schools were functioning, to 5.7 in 1930. Improvements in the standards of medical education are reflected in this decrease of failures in licensing examinations. With the migration of European physicians to this country beginning in 1936 and the resultant licensure difficulties, the proportion of failures began to rise, reaching another peak of 20.7 per cent in 1940. In the last two years the number of foreign graduates and graduates of unapproved schools applying for licensure has considerably decreased.

In analyzing this table it should be remembered that the figures refer to examinations given rather than to individuals examined.

GRADUATES OF APPROVED SCHOOLS AND OTHERS REGISTERED, 1922-1946

The educational fitness of physicians registered for the practice of medicine in twenty-five years is recorded in table 23. In the computation of these figures, schools rated as class A and B by the Council on Medical Education and Hospitals of the American Medical Association since 1907 are classified as approved. In the column "Others" are included individuals who graduated prior to 1907, when the first classification of schools was made, graduates of foreign faculties of medicine, class C graduates, osteopaths given recognition by medical licensing boards and graduates of schools not approved by the Council. In 1928 the classification A, B and C by the Council was discontinued and a list of approved medical schools has since been maintained.

TABLE 23.—*Graduates of Approved Schools and Others Registered, 1922-1945*

1938	8,315	87.1	1,230	12.9	9,545
1939	8,067	86.2	1,298	13.8	9,365
1940	7,781	85.0	1,375	15.0	9,156
1941	7,767	88.1	1,049	11.9	8,816
1942	7,290	84.9	1,298	15.1	8,588
1943	8,639	87.8	1,188	12.2	9,827
1944	7,733	89.9	870	10.1	8,603
1945	8,227	91.9	730	8.1	8,957
1946	15,588	94.9	835	5.1	16,423
Total	185,809	89.0	23,084	11.0	208,893

There were 16,423 candidates registered in 1946, of whom 15,588 (94.9 per cent) represented graduates of approved schools and 835 (5.1 per cent) were in the second group.

In the twenty-five year period 208,893 were registered, including 185,809 approved graduates (89 per cent) and 23,084 others (11 per cent). Since 1922 the annual number of graduates of approved schools has increased well beyond 4,500, representing 80 to 90 per cent of those annually registered. Until the influx of foreign graduates in 1936, those in the second group subsequent to 1924 were fewer than 1,000. The number in this group was considerably decreased in 1945, but in 1946 there were 105 more registered than in the preceding year.

GRADUATES OF UNAPPROVED SCHOOLS REGISTERED, 1941-1946

Recorded in table 24 are data regarding graduates of institutions which do not meet the minimum essentials of an acceptable medical school as outlined by the House of Delegates of the American Medical Association and administered by the Council on Medical Education and Hospitals. This table shows the numbers registered as medical licentiates in the United States and Hawaii by written examination or endorsement of credentials in the past six years, 1941 to 1946 inclusive. Figures are given separately for those licensed by written examination and by endorsement of credentials. In the six years shown, twenty-one states and Hawaii registered 1,054 by examination and 30 by endorsement of credentials. In 1946 there were 211 registered, 204 by examination and 7 without written examination in Arizona, Florida, Illinois, Iowa, Massachusetts, Mississippi, Nebraska, New York, Ohio, Texas, Virginia and Washington.

Illinois, which accepts for licensure the graduates of an unapproved school located in that state, and Massachusetts licensed the largest number of graduates of unapproved schools. In the latter state the institutions referred to in the table were not granted approval by the State Approving Authority of that state. Matriculants after Jan. 1, 1941 are not eligible for licensure in Massachusetts. Regulations have become effective in New York, Ohio and Virginia providing for licensure of unapproved graduates under certain conditions. In the latter two states they apply to physician veterans only. In some states (Mississippi, for example) licensure is sometimes obtained by special act of the legislature.

GRADUATES OF SCHOOLS OF OSTEOPATHY REGISTERED BY MEDICAL EXAMINING BOARDS, 1941-1946

The numbers of graduates of schools of osteopathy granted the privilege of practicing medicine or surgery or both by the examining boards of fourteen states and the District of Columbia for six years (1941-1946) are given in table 25. There have been 954 such individuals registered since 1941, 802 by examination and 152 without examination. In 1946 there were 201 so registered, 158 by examination and 43 by reciprocity in thirteen states—Colorado, Connecticut, Delaware, District of Columbia, Indiana, New Jersey, New York, Ohio, Oregon, Texas, Virginia, Wisconsin and Wyoming.

Following is a summary of the situation in the fifteen states and the District of Columbia providing for the licensure of osteopaths by the medical examining board:

In Colorado an osteopath receives a license to practice medicine. In Connecticut any registered osteopath may practice either medicine or surgery or both, as the case may be, if he passes a satisfactory examination before the medical examining board. In Delaware osteopaths are licensed as "osteopathic physicians." In the District of Columbia, osteopaths are granted the right to practice surgery. In Indiana the licenses issued to osteopaths, under a 1945 amendment to the medical practice act authorize the holders to practice medicine and surgery. Licentiates in osteopathy prior to 1945 have now been authorized to practice osteopathy, surgery and obstetrics. In Massachusetts the medical practice act, by definition, includes osteopathy in the practice of medicine and does not differentiate the type of license issued to an osteopathic applicant. According to a law passed in Nebraska in 1943 "any person now licensed to practice osteopathy may, if application is made prior to July 1, 1948 and upon payment of the prescribed fee, take the first regular examination given after the application is made before the Board of Examiners in Medicine. . . . If successful he or she shall receive a license to practice medicine and surgery in the state." In New Hampshire, osteopaths are granted the right to practice medicine and surgery.

In New York a law approved April 10, 1946 provides that any osteopathic licentiate who had obtained the additional right to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics and biological products or any applicant who has met

or shall meet all the preliminary and professional requirements as required as of September first, nineteen hundred thirty-six and has satisfactorily passed or shall satisfactorily pass the regular medical licensing examination shall be granted the right to practice medicine without limitation as defined by the statutes of the State of New York.

New Jersey provides that osteopaths licensed prior to Nov. 1, 1941 who furnish proof prior to that date of having served for a period of two years as an intern or resident surgeon in an osteopathic or medical hospital approved by the board of medical examiners, of having completed a postgraduate course of two years in a college of osteopathy or medicine approved by the board or of having had at least three years of practice in a hospital approved by the board can be admitted to an examination in pharmacology, therapeutics and surgery and, if successful, can obtain a license to practice medicine and surgery. Since 1941 all osteopathic applicants who have met the requirements of the medical practice act have been licensed to practice medicine and surgery.

A law passed in Ohio in 1943 gives osteopaths who obtain their licenses under that act the right to practice osteopathic medicine and surgery. In Oregon they are granted the right to practice "in the subjects" covered by the examination, which includes surgery. The medical practice act of Texas provides for the issuing of a license to practice medicine only and osteopaths are issued licenses unrestricted in scope. In Virginia osteopaths may obtain the right to use drugs and perform surgery with the use of instruments if they satisfy the

* Refer to chart of "Reciprocity and Endorsement Policies" for further data.

1. Certificate of National Board of Medical Examiners or licensure in country in which school of graduation is located or in the country of his nativity.
2. Internship or one year in medical school in United States.
3. Certificate of National Board of Medical Examiners.
4. For graduates of last five years; if more than five years $50.
5. Residence of one year in Delaware.
6. If similar privileges are accorded licentiates of District of Columbia by licensing agency of jurisdiction from which applicant comes.
7. Senior year in class A medical school in United States or one year assistant residency in approved hospital in United States.
8. Not required if country in which applicant is licensed will admit to practice citizens of the United States licensed to practice in some state or upon proof of requirements similar to those required by California of graduates of foreign medical schools.
9. Enemy aliens not accepted.
10. Application must be filed six months prior to date of examination.
11. Licensed to practice medicine and surgery in country in which school of graduation is located, otherwise required to complete senior year in approved medical school in United States.
12. Diplomates of National Board of Medical Examiners eligible.
13. License to practice medicine and surgery in the country in which the school of graduation is located.
14. Matriculants after Jan. 1, 1940 not accepted.
15. At the discretion of the board.
16. Internship and graduate work.
17. Internship completed in foreign countries after July 1, 1934 not acceptable.
18. Rotating internship in approved hospital in the United States or completion of senior year in class A medical school in the United States.
19. These requirements apply also to graduates of Canadian schools.
20. Graduates from foreign medical colleges accepted if they present also a diploma from an approved medical school in the United States.
21. Provided standard was the same as California on the same date.
22. Degree from an American medical college acceptable to the Medical Council of Delaware required.
23. Diplomates of the National Board of Medical Examiners accepted. Citizenship required.
24. In lieu of internship, certificate from three graduates of applicant's medical school licensed to practice medicine in United States accepted.
25. Effective July 1, 1943.
26. Homeopathic board requires one year internship in homeopathic hospital in the United States.
27. Will consider limited license for applicant with acceptable credits from National Board of Medical Examiners and states maintaining reciprocity.
28. No applications accepted from countries other than England (certain schools), Ireland, Scotland and Australia.

board of medical examiners that they are qualified to do so. Wisconsin grants osteopaths the privilege to practice surgery, and in Wyoming the statutes contain no specific provision for the licensing of osteopaths. The medical practice act of the latter state provides that the certificate issued to all applicants "shall be deemed licenses to practice medicine in all branches in which the applicant has taken examination in the state."

PHYSICIANS EXAMINED ON BASIS OF CREDENTIALS OBTAINED IN COUNTRIES OTHER THAN THE UNITED STATES AND CANADA

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. It does not attempt to evaluate institutions which it is not in a position to visit to determine whether they meet the minimal essentials of an acceptable medical school as outlined by the Council. This was true even before the war.

For a period of twelve years beginning in 1926 the credentials of physicians coming from abroad were verified by the Council through official correspondence with the medical schools directly or through the diplomatic services. Prior to the onset of the war in Europe it was necessary to discontinue this effort, and on the licensing boards rests the responsibility of evaluating the credentials presented by these graduates. In the 1942 edition of the American Medical Directory a symbol in the biographic data of foreign graduates indicates when the information given is the licensing board's record of the credential accepted as meeting the educational qualifications for licensure. The absence of the symbol may be interpreted to indicate that official verification is on file in the office of the Council.

A committee composed of representatives of various interested organizations has been formed to consider the problem of evaluation of foreign credentials submitted by physicians and students from foreign medical schools. The first meeting of the committee was held in February 1947. No positive recommendations emerged from this meeting, but the discussions will be continued and an attempt made to obtain pertinent data pertaining to schools and educational procedures in all countries.

The requirements of candidates for medical licensure in the United States, Alaska, Hawaii and Puerto Rico on the basis of credentials obtained in countries other than the United States and Canada are given in table 26. Seventeen states report that the holders of such credentials are not eligible for licensure. Nineteen states, Alaska, Hawaii and Puerto Rico require full citizenship and ten states naturalization papers as a condition precedent to taking the examination. The District of Columbia and Indiana make no reference to citizenship. In some states the recognition or nonrecognition of such individuals is by rule of the board; in others the provision is by statute. Ten states and Alaska which will admit foreign graduates to practice, require a certificate from the state board of examiners in the basic sciences. In twenty states, Alaska, Hawaii and Puerto Rico an internship in a hospital in the United States is a prerequisite. Additional qualifications of individual states are given in footnotes. Tennessee, which heretofore did not accept for licensure graduates of foreign faculties of medicine, has been added to this table in 1946.

Table 27 presents figures relating to physicians examined on the basis of credentials obtained in countries other than the United States and Canada by licensing boards in 1946. The figures represent both American and foreign born physicians educated abroad. Eighty-six faculties of medicine and four licensing corporations of sixteen European countries and fourteen other countries are represented. There were 494 physicians examined by twenty states, the District of Columbia, Hawaii and Puerto Rico, of whom 220 passed and 274, 55.5 per cent, failed. Graduates of the University of Vienna represented the largest group, 67, who were examined in twelve states, with a failure percentage of 59.7. Eight states examined 32 graduates of the University of Berlin, of whom 56.2 per cent failed. Forty physicians who hold the registrable qualification, Licentiate of the Royal College of Physicians and of Surgeons, Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow were examined in four states, and 30 per cent failed. Fifteen or more graduates of the universities of Havana, Bologna, Rome and Lausanne also were examined in the United States last year. Fewer than 5 graduates of sixty-five foreign schools appeared for licensure last year.

TABLE 28.—*Physicians Examined on the Basis of Credentials Obtained in Countries Other Than the United States and Canada, 1930-1946*

Year	Number Examined	Passed	Percentage Failed
1930	167	92	44.9
1931	158	91	42.4
1932	182	96	47.3
1933	200	129	35.5
1934	285	170	40.2
1935	437	303	30.7
1936	588	382	35.0
1937	920	637	30.8
1938	1,164	716	38.5
1939	1,691	839	50.4
1940	2,088	948	54.7
1941	1,717	698	59.2
1942	1,630	890	45.4
1943	1,031	518	49.8
1944	691	325	53.0
1945	475	209	56.0
1946	494	220	55.5
Totals	13,918	7,263	47.8

The greatest number of foreign graduates examined by any one state was 315 in New York, of whom 106 passed and 209 (66.3 per cent) failed. No other state tested more than 42 of these physicians. Fewer than 5 were examined by nine states.

Table 28 records the number of graduates of faculties of medicine abroad examined for medical licensure in the United States in the seventeen years 1930 to 1946 inclusive. In this period 13,918 were examined, of whom 7,263 passed and 47.8 per cent failed. Although there has been a considerable reduction in the number of foreign graduates seeking licensure in recent years, the percentage of failures has not changed significantly. The greatest number of failures occurred in 1941, when 59.2 per cent failed. At no time in this seventeen year period did fewer than 30.7 per cent fail.

In 1936 the number of foreign graduates began to increase, so that in 1940 there were over three times

as many tested as in 1936. Since 1940 there have been annual decreases, though the number examined in 1946 was slightly more than in 1945, but the annual total is still in excess of the number licensed annually prior to 1935 and before the increased migration of foreign physicians to this country from Europe.

Officers of State Boards of Medical Examiners

Alabama	Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.
Arizona	Dr. J. H. Patterson, 826 Security Bldg., Phoenix.
Arkansas	Dr. L. J. Kosminsky, Texarkana.
California	Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

New Jersey	Dr. E. S. Hallinger, 28 W. State St., Trenton.
New Mexico	Dr. Le Grand Ward, 141 Palace Ave., Santa Fe.
New York	Dr. J. L. Lochner, 315 State Education Bldg., Albany.
North Carolina	Dr. Ivan Proctor, 226 Hillsboro St., Raleigh.
North Dakota	Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.
Ohio	Dr. H. M. Platter, 21 W. Broad St., Columbus.
Oklahoma	Dr. F. C. Gallaher, 813 Braniff Bldg., Oklahoma City.
Oregon	Miss L. M. Conlee, 608 Failing Bldg., Portland 4.
Pennsylvania	Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.
Rhode Island	Mr. Thomas B. Casey, 366 State Office Bldg., Providence.
South Carolina	Dr. N. B. Heyward, 1329 Blanding St., Columbia.
South Dakota	Dr. Gilbert Cottam, Capitol Bldg., Pierre.
Tennessee	Dr. H. W. Qualls, 130 Madison Ave., Memphis 3.
Texas	Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.
Utah	Mr. W. R. McEntire, 324 State Capitol Bldg., Salt Lake City.
Vermont	Dr. F. J. Lawliss, Richford.
Virginia	Dr. K. D. Graves, 30½ Franklin Rd., S.W., Roanoke.
Washington	Miss Virginia Wotherspoon, Olympia.
West Virginia	Dr. N. H. Dyer, State Capitol, Charleston 5.
Wisconsin	Dr. C. A. Dawson, Tremont Bldg., River Falls.
Wyoming	Dr. G. M. Anderson, Capitol Bldg., Cheyenne.
Alaska	Dr. W. M. Whitehead, Box 140, Juneau.
Canal Zone	Dr M. C. Stayer, Balboa Heights.
Hawaii	Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.
Puerto Rico	Mr. Luis Cueto Coll, Parada 22, Santurce.
Virgin Islands	Dr. K. Knud-Hansen, Charlotte Amalie.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

A basic science law provides for the establishment of a board of examiners and requires that each person who desires to practice the healing arts appear before that board and demonstrate his knowledge of the basic sciences. Such boards are distinct from licensing boards. A certificate of proficiency in the basic sciences does not authorize the possessor to practice the healing art; it enables him only to apply for licensure so to practice.

A basic science certificate is a prerequisite for licensure in seventeen states, the District of Columbia and Alaska. Alaska was added to this group by the Territorial Legislature on April 3, 1946. The first states to adopt such legislation were Connecticut and Wisconsin in 1925. Other states comprising the group, together with the year of enactment of their basic science law, are recorded in table 29.

TABLE 29.—*States Having Basic Science Laws and Year of Enactment*

The subjects in which examinations are conducted in the respective states, the District of Columbia and Alaska, as shown in table 30, are specified by statute. The examining boards are not authorized to add any subjects or to refrain from giving an examination in any subject specified by law, although the laws in some instances provide for certification without examination by the endorsement of a basic science certificate issued in another state, passing the National Board examination or the acceptance of examinations in the required subjects by a licensing board.

All nineteen boards examine in anatomy, pathology and physiology, seventeen examine in chemistry, fifteen in bacteriology, nine in hygiene, two in diagnosis and one in public health.

The results of examinations held and the number of certificates issued on the basis of reciprocity or endorsement during 1946 are presented in tables 31 and 32 as reported by the respective boards. A candidate in applying for a basic science certificate is not required by law to mention his school of practice. However, by checking the biographic records of physicians and medical student records of the American Medical Association and various directories it has been possible to determine the profession of the majority of candidates. Thus it has been possible to tabulate the figures in four groups, namely physicians and medical students, osteopaths, chiropractors and unclassified applicants. The latter category includes those for whom it was not possible to determine the profession represented. In Rhode Island doctors of dentistry represent the unclassified group. It may be assumed that others in this unclassified group include osteopaths, chiropractors and also naturopaths who have not been identified by the reference material available.

The nineteen basic science boards in operation in 1946 examined a total of 3,333 candidates, table 31.

Wisconsin	202	7	1	0	210	216	11	3	0	230	440
Totals	2,391	106	14	47	2,558	1,308	153	12	1	1,474	4,032

Physicians and medical students represent the greatest number examined. There were 2,937 in this group. There were also examined 196 osteopaths, 40 chiropractors and 77 in the unclassified group. Of all applicants 23.3 per cent failed, of the physicians and medical students examined 18.7 per cent failed, osteopaths 45.1 per cent, chiropractors 65 per cent and unclassified 39 per cent. The basic science board of Florida examined the greatest number, 407, representing 397 physicians and medical students and 10 others with 24.1 per cent failures. Iowa, Michigan and Minnesota examined more than 300. The percentage of failures in these states was 58.2, 34.9 and 16.2 respectively. New Mexico and Alaska reported no failures.

Osteopaths were examined in Arkansas, Colorado, Connecticut, District of Columbia, Florida, Iowa, Michigan, Minnesota, New Mexico, Oregon, Tennessee, Washington and Wisconsin. Chiropractors appeared for certification before the boards in Arkansas, Connecticut, District of Columbia, Florida, Iowa, Michigan, Minnesota, Rhode Island, Washington and Wisconsin.

It is the policy of the Arizona Board of Examiners in the Basic Sciences in reporting results of its examinations to omit the names of applicants who fail examinations. The number who fail are therefore recorded only in the total column. Iowa in 1946 reported failures by total number only in reporting results of one of their examinations.

* Nature of practice undeterminable since names of failures not supplied.

† Nature of practice of 63 undeterminable since names of failures not supplied.

Twelve states, the District of Columbia and Alaska granted basic science certificates without examination, by reciprocity, endorsement, waiver or exemption. There were 1,474 certificates awarded by this method in 1946. By both examination and endorsement, 4,032 certificates of proficiency were issued. The number of successful candidates in these two groups by states are recorded in table 32. Among the successful candi-

dates

dates were 3,699 physicians or medical students, 259 osteopaths, 26 chiropractors and 48 others. Wisconsin certified the most applicants without examination, 230, of whom 216 were physicians, 11 osteopaths and 3 chiropractors. Florida and Washington have no reciprocal relations. None were certified without examination in 1946 in Connecticut, New Mexico and Rhode Island.

OFFICIALS OF BASIC SCIENCE BOARDS

Arizona—Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.
Arkansas—Mr. L E. Gebauer, 701 Main Street, Little Rock.
Colorado—Esther B. Starks, D. O., 1459 Ogden Street, Denver.
Connecticut—Mr. C M. Bakewell, 250 Church Street, New Haven.
District of Columbia—Dr. G. C Ruhland, 6012 E. Municipal Building, Washington
Florida—Dr M. W. Emmell, University of Florida, Gainesville
Iowa—Dr. Ben H. Peterson, Coe College, Cedar Rapids
Michigan—Miss Eloise LeBeau, 101 N. Walnut Street, Lansing.
Minnesota—Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.
Nebraska—Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9
New Mexico—Miss Marion M. Rhea, 114 E Marcy St, Santa Fe
Oklahoma—Dr. Frank C. Gallagher, 813 Braniff Bldg, Oklahoma City.
Oregon—Mr. C D Byrne, University of Oregon, Eugene
Rhode Island—Mr Thomas B. Casey, 366 State Office Building, Providence
South Dakota—Dr. G. M. Evans, Yankton.
Tennessee—Dr. O. W. Hyman, 874 Union Avenue, Memphis.
Washington—Mr. Harry C Huse, Olympia
Wisconsin—Mr. William H Barber, Watson and Scott Sts, Ripon

Altogether 4,032 candidates received basic science certificates in the seventeen states, the District of Columbia and Alaska, ranging from 5 in Alaska to 443 in Minnesota, while 775 failed after examination during the year 1946.

Table 33 records the number of candidates examined and certified, and the number certified without examination by basic science boards in twenty years, 1927 to 1946 inclusive. In 1927 when five boards were functioning, there were 305 examined, of whom 8.5 per cent failed, and 22 others, of whom 31.8 per cent failed. In 1946 there were examined 2,937 physicians with 18.7 per cent failures and 313 others, of whom 46.6 per cent failed.

In the twenty year period 25,434 physicians and medical students were examined, of whom 21,940 were successful in their examinations. In the same period 3,847 other practitioners took the test and 1,962 were successful. In this period 5,314 physicians and 1,082 others were certified without examination. In twenty years 30,298 certificates have been granted to 27,254 physicians and to 3,044 other practitioners.

Alaska was added to the group requiring a basic science certificate as a prerequisite to the practice of the healing art in 1946. The law provides for the issuance of a certificate without examination to diplomates of the National Board of Medical Examiners and to those persons who have passed examinations before an examining board of a state or foreign country who will accord a like privilege to certificants of the basic science board of Alaska. No other new basic science legislation was enacted in the United States in 1946.

The principle of basic science legislation is to provide a means of insuring that all who seek licensure to care for sick and injured persons shall first possess a reasonable knowledge of the sciences fundamental to the healing art. The enforcement of such laws affects mostly the group classified as "other practitioners." This is particularly significant when one takes into account that the testing of individuals for basic science registration is made by nonmedical examiners. The results demonstrate that, in general, practitioners other than regular physicians are poorly equipped in the fundamentals of medicine and should not be entrusted to care for the health of the people.

Efforts are being made by the American Association of Basic Science Boards to provide information based on experience to states contemplating new basic science board legislation and to develop procedures to facilitate reciprocity arrangements. In some instances basic science certification by reciprocity is unnecessarily difficult because of otherwise unimportant differences in the laws of the various states. A committee of three representatives of the Federation of State Medical Boards has been appointed to meet with a similar committee representing the state basic science boards in an effort to better integrate the operation of basic science laws with the system of medical licensure now existing in the various states. This committee has not as yet reported the results of its findings.

NATIONAL BOARD OF MEDICAL EXAMINERS

The certificate of the National Board of Medical Examiners is accepted as an adequate qualification for a medical license by the licensing authorities of forty-four states, the District of Columbia, Alaska, Hawaii, Puerto Rico and the Canal Zone. The National Board certificate is not recognized at present by the licensing boards of Florida, Montana, Nevada and Wisconsin. Nevada has temporarily suspended reciprocal relations in medical licensure. The licensing board in Louisiana exempts diplomates of the National Board from the state examination if they have been licensed in a state with which Louisiana reciprocates. Additional examinations are required by some of the state licensing boards. These are oral examinations in Illinois, Maine, Rhode Island and Wyoming, a brief supplemental written examination in Michigan, a rotating internship in Pennsylvania and two years of medical practice in Delaware The states, territories and possessions which will endorse the certificate of the National Board of Medical Examiners are recorded in table 34.

The basic science boards of Connecticut, Iowa, Minnesota, Nebraska, Oklahoma, Tennessee, the District of Columbia and Alaska honor the examination of the National Board and give a qualifying certificate to its diplomates without further examination. South Dakota exempts medical officers of World War II from the basic science requirement.

Diplomates of the National Board are admitted to the final examination of the Examining Board in England, the Triple Qualification Board of Scotland and the Conjoint Board in Ireland. These final examinations are both written and oral and correspond to parts II and III of the National Board. The National Board, in turn, admits the diplomates of these boards directly to parts II and III of its examination, provided they hold a degree in medicine from an acceptable university. The certificate of the National Board has in the past been recognized in Lebanon (Syria), Spain and Turkey, under certain conditions in South Africa and in other foreign countries.

Diplomates are exempt from some of the qualifications required by the United States Public Health Service.

Requirements for admission to the National Board examinations include a standard four year high school course, two years of acceptable college work including English, physics, chemistry, biology and a foreign language and a medical education satisfactorily completed in an approved school in this country or Canada. Graduates of the university medical schools of Great Britain and Ireland are admitted to the examination provided these graduates have been licensed to practice in the country in which the school attended is located.

The almost universal recognition of the examinations of the National Board is evidenced by the acceptance of the board's examinations by many medical schools as part of their own examination and promotion procedure. At some of the schools the students are required to pass part I at the end of the second year and part II at the end of the fourth year. Other schools require that part II be passed at the end of the fourth year. Candidates who fail to pass the National Board examinations are given a supplemental examination at most schools. The schools that require their students to take the National Board's examinations under one plan or another are Albany, Boston, Buffalo, Duke, George Washington, Harvard, Long Island, New York Medical College and Yale. In addition to the schools named there are a few others at which those students who voluntarily take and pass the National Board's examinations, either in part I or in part II, are excused from the corresponding final school examinations. This group of schools includes Colorado, Georgetown, Illinois, Loyola, Minnesota, Pennsylvania, Tufts and the Woman's Medical College. Regarding this plan the board states that "this practice places additional work and responsibility on the National Board of Medical Examiners. The board believes, however, that such use of its examinations is of definite value to the board because it necessitates that the examination be kept in close step with present medical education in this country. It appreciates the confidence in the fairness and thoroughness of its examinations that is implied by the substitution of the board's examinations for the former college comprehensive examination."

In the following paragraphs data are presented for the twenty-eighth consecutive year regarding the examinations conducted and the issuance of certificates by the National Board of Medical Examiners. These data are based on official reports received periodically from the executive office of the board. The awarding of certificates to candidates forms a part of their biographic records maintained by the American Medical Association.

The first examination was given by the National Board in October 1916. From that date and up to and including a test held in June 1921, eleven examinations were given and 268 candidtaes were certified. The results of each examination during this period are given in table 35. These data, together with subsequent tables containing figures to and including 1946, have been presented annually in THE JOURNAL for twenty-nine consecutive years.

Since 1922 the examination of the National Board has been divided into three separate parts, which must be taken and completed in the following sequence: part I, consisting of a written examination in the basic sciences; part II, a written examination in five major clinical subjects, and part III, a clinical and practical examination in six major clinical divisions and their component subjects or subdivisions.

The tables that are hereinafter presented enumerate the results of examinations in parts I, II and III for each calendar year since 1922, including those who passed and failed examinations and those certified.

Three examinations each were given in parts I and II in 1946 in various approved medical schools throughout the country. Examinations in part III are given under the direction of local subsidiary boards at times sufficiently frequent to accommodate all eligible candidates. Subsidiary boards have been organized for this purpose in twenty-four centers. Examinations in part III were held in 1946 during the months of March, April, June, October, November and December.

TABLE 35.—*National Board Examinations, 1916-1921*

Date		Total Examined	Failed	Percentage Failed
October	1916	10	5	50.0

June	1921	40	3	7.5
Totals		325	57	17.5

A candidate is eligible for part I who has met the premedical requirements and has completed successfully the first two years of work in an approved medical school. An incomplete examination is allowed candidates taking part I at the end of their second medical year in schools whose third year curriculums include courses in one or two subjects of this part. These examinations in the subjects not yet completed are therefore postponed and may be taken at any examination period after the candidate has completed them in his *medical school.* They are recorded in these statistics under the heading "Incomplete Examinations" and are excluded from the calculations referring to the percentage of failures. Any candidate not entitled to take an incomplete examination in part I may, if he so elects, take a divided examination by writing any four subjects at one time and the remaining two within thirteen months.

A candidate is eligible for part II who has passed part I and has completed successfully a four year medical course in an approved medical school.

The figures in tables 36 and 37 cover details of each examination given during 1946 and since 1922 and include some who fail and are reexamined during the same year and those who pass parts I and II in the same year. They represent, therefore, examinations conducted and not individuals examined.

1945	1,599	1,565	0	34	2.1
1946	1,824	1,781	0	43	2.4
Totals	19,846	18,582	46	1,218	6.2

During the year 1946, 3,148 examinations were given in part I; 1,695 passed and 264, or 13.5 per cent, failed. There were 1,189 incomplete examinations given. In calculating the percentage of failures these incomplete examination figures are excluded. In part II, 1,824 examinations were held; 1,781 passed and 43, or 2.4 per cent, failed. Incomplete examinations are only rarely given in part II. There were none given in 1946.

There have been 38,166 examinations given in part I since 1922 and 19,846 in part II. During this period 22,992 passed part I and 18,582 passed part II. In twenty-five years there have been 3,852 failures in part I, 14.3 per cent, and 1,218 failures in part II, 6.2 per cent. The wartime accelerated program in operation in all medical schools is evidenced by the increase in the number of candidates taking the examinations since 1942. The greatest number of examinations in part I were given in 1944 and in part II in 1943.

TABLE 38.—*National Board Examinations in Part III, 1922-1946*

	Total Examinations	Passed	Failed	Percentage Failed

1938	706	682	24	3.4
1939	770	729	41	5.3
1940	792	771	21	2.7
1941	910	885	25	2.7
1942	1,054	1,041	13	1.2
1943	1,230	1,213	17	1.4
1944	1,167	1,145	22	1.9
1945	1,244	1,231	13	1.0
1946	1,632	1,611	21	1.3
Totals	15,543	15,066	477	3.1

A candidate is eligible for part III who has passed parts I and II, received his M.D. degree and has satisfactorily completed an internship in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or by the Canadian Medical Association or has served in a laboratory acceptable to the National Board. In 1946, 1,632 tests were given in part III; 1,611 passed and 21, 1.3 per cent, failed. Results of examinations given in this part in twenty-five years are given in table 38 and indicate that 15,543 were tested, of whom 15,066 were granted certificates. The percentage of failures in this part in twenty-five years was 3.1. Since the inception of the National Board in 1916, 15,334 certificates have been awarded.

Physicians who earn the certificate are designated diplomates of the National Board and are privileged to use the designating initials D.N.B.

The figures thus far presented represent examinations given. The number of individuals tested during any one year is recorded for the twenty-five year period in table 39. The classification as "Passed" or "Failed" in cases in which more than one examination has been taken in a given year was based on the results of the last examination during the year in question. For example, if in 1946 a candidate passed part I but later in 1946 failed part II he is computed in the tabulation as having failed. On this basis figures computed indicate that there were 5,912 who took at least one of the tests of the National Board in 1946, as compared with 525 in 1922. The trend has been steadily upward. Last year the number of candidates was 298 greater than in the previous year, which exceeded the 1944 figure by 549. In all, 65,498 individuals were examined in one or more of the annual examinations in the twenty-five years shown, of whom 51,759 passed, 9,059 took incomplete examinations and 4,680, or 8.3 per cent, failed.

Table 39.—*Parts I, II and III, Excluding Duplications, 1922-1946*

	Total Examined	Passed	Incomplete	Failed	Percentage Failed
1922	525	381	58	86	18.4
1923	775	594	79	102	14.7
1924	976	736	69	153	16.8
1925	1,167	915	50	202	18.1
1926	1,161	930	105	126	11.9
1927	1,248	947	142	159	14.4
1928	1,430	1,101	211	118	9.7

1936	2,517	1,989	353	175	8.1
1937	2,735	2,151	397	187	8.0
1938	2,992	2,308	493	191	7.6
1939	3,221	2,476	443	302	10.9
1940	3,188	2,597	363	228	8.1
1941	3,318	2,749	332	237	7.9
1942	3,607	3,014	391	202	6.3
1943	4,514	3,671	606	237	6.1
1944	5,363	4,235	759	369	8.0
1945	5,614	4,468	886	260	5.5
1946	5,912	4,730	898	284	5.7
Totals	65,498	51,759	9,059	4,680	8.3

The 1,611 physicians certified as diplomates in 1946 represented sixty existing medical schools and one extinct medical school in the United States, six in Canada and six foreign universities, as shown in table 40. A few of these foreign graduates were diplomates from medical schools in continental Europe who had registered before the National Board discontinued admitting graduates of these schools.

Diplomates licensed to practice medicine on the basis of their credentials increased from 2 in 1917 to 2,654 in 1946 and 12,682 have been so licensed since the National Board was formed. However, 15,066 have received the certificate of the board. It would appear that 2,384 have not used the credentials as a licensing medium. In 1946 diplomates were granted licenses to practice medicine on the basis of their credentials in 43 states, the District of Columbia, Hawaii and Puerto Rico. The number so registered in each state is reported in table 41.

The constitution of the National Board of Medical Examiners provides for a membership of thirty representing the federal services, the Federation of State Medical Boards of the United States, the Association of American Medical Colleges, the Council on Medical Education and Hospitals of the American Medical Association and members elected at large. The acting president of the board is Borden S. Veeder, M.D., the medical secretary, J. S. Rodman, M.D., and the executive secretary and treasurer, Mr. Everett S. Elwood. The address of the board is 225 South 15th Street, Philadelphia.

EXAMINING BOARDS IN THE MEDICAL SPECIALTIES

The "Essentials for Approved Examining Boards in Specialties," originally published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION July 7, 1934, have been revised, particularly as they now refer to historical background, organization of boards, their operation and procedures for obtaining approval. This revision was officially approved by the House of Delegates of the American Medical Association on Dec. 9, 1946. These "Essentials" are as follows:

ESSENTIALS FOR APPROVED EXAMINING BOARDS IN SPECIALTIES

INTRODUCTION

The American Board of Ophthalmology, the first of the examining boards in the specialties, was incorporated in 1917. Four additional boards were organized by 1933 (Otolaryngology in 1924, Obstetrics and Gynecology in 1930, Dermatology and Syphilology in 1932 and Pediatrics in 1933).

In 1933 the House of Delegates of the American Medical Association adopted a resolution authorizing the Council on Medical Education and Hospitals "to express its approval of such special examining boards as conform to the standards of administration formulated by the Council" and providing for the employment of "the machinery of the American Medical Association, including the publication of its Directory, in furthering the work of such examining boards as may be accredited by the Council."

In 1933-1934 the Advisory Board for Medical Specialties was organized with representation from each of the approved boards to "act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists." The Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties work in close collaboration through joint meetings and frequent conferences.

PURPOSE AND FUNCTIONS OF A SPECIALTY BOARD

An American Board in a specialty is organized (*a*) to assist in improving the quality of graduate education in that field, (*b*) to establish minimum educational and training standards in the specialty, in conformity with the general provisions of these "Essentials," (*c*) to determine whether candidates have received adequate preparation as defined by the Board, (*d*) to provide comprehensive examinations to determine the ability and fitness of such candidates and (*e*) to certify to the competence of those physicians who have satisfied the requirements of the board, as a protection to the public and profession.

ORGANIZATION

An examining board in a specialty, to be approved by the Council on Medical Education and Hospitals, should represent a recognized and distinct specialty or well defined field of medicine. It should be composed of representatives of the national organizations in the field as well as the related section of the American Medical Association. The board should be incorporated.

DEFINITION OF SPECIAL FIELDS

The following branches of medicine at present are recognized as suitable fields for the certification of specialists. In each case the symbol employed in designating the specialists in the Directory of the American Medical Association is given (A.B. 1, and so on). Certain of the boards also certify candidates in subspecialties, as indicated by footnotes:

	Name of Board	Year of Incorporation
A.B.	1. American Board of Pediatrics[1]	1933
A.B.	2. American Board of Psychiatry and Neurology	1934
A.B.	3. American Board of Orthopaedic Surgery	1934
A.B.	4. American Board of Dermatology and Syphilology	1932
A.B.	5. American Board of Radiology	1934
A.B.	6. American Board of Urology	1935
A.B.	7. American Board of Obstetrics and Gynecology	1930
A.B.	8. American Board of Internal Medicine[2]	1936
A.B.	9. American Board of Pathology	1936
A.B.	10. American Board of Ophthalmology	1917
A.B.	11. American Board of Otolaryngology	1924
A.B.	12. American Board of Surgery[3]	1937
A.B.	13. American Board of Anesthesiology	1938
A.B.	14. American Board of Plastic Surgery	1937
A.B.	15. American Board of Neurological Surgery	1940

---

[1] Also certifies specialists in allergy.

[2] Also certifies specialists in allergy, cardiovascular disease, gastroenterology and tuberculosis.

[3] Also certifies specialists in proctology.

QUALIFICATIONS OF CANDIDATES

Each applicant for admission to the examination should be required to present evidence that he has met the following standard:

A. General Qualifications.

1. Satisfactory moral and ethical standing in the profession.
2. A license to practice medicine in a state, territory or possession of the United States.

B. Professional Education.

1. Graduation from a medical school of the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association. Candidates who submit credentials from institutions outside of the United States and Canada should be required to pass the examination of the National Board of Medical Examiners.
2. Completion of an internship of not less than one year in a hospital approved by the same Council.

C. Special Training.

1. A period of special training after the internship, preferably three years, in clinics, dispensaries, hospitals or laboratories approved by the Council on Medical Education and Hospitals and the respective specialty board as competent to provide a satisfactory training in the special field of study. In individual instances specialty boards may grant training credit for work done in preceptorships. Candidates whose special training has been received outside of the United States should submit credentials satisfactory to the examining boards. Credits for military service may be granted by individual boards.
2. This specialized training preparation shall likewise:
    (*a*) include satisfactory graduate training in the basic sciences which is considered by the American Board necessary to the proper understanding of the specialty in question;
    (*b*) be supplemented by an additional period of not less than two years of training and/or practice in the special field concerned;
    (*c*) be evaluated by examinations which should include the basic medical sciences as well as the clinical, laboratory and public health aspects of the specialty.

ESTABLISHMENT OF AN ACCEPTABLE SPECIALTY BOARD

In considering the organization of an American Board in a special field of medicine seeking recognition by the Council on Medical Education and Hospitals of the American Medical Association the procedure is as follows:

A. The application should be presented to the Advisory Board for Medical Specialties. This board in turn shall fully inform the Council on Medical Education and Hospitals regarding the application.

B. The application after being received from the Advisory Board for Medical Specialties will carefully be deliberated by the Council, due consideration being given to the need for a new board, the relationship of that board to the existing boards and the adequacy of the proposed educational programs and available facilities for the preparation of physicians for the certification examinations.

C. The Council will approve new boards only after recommendation by the Advisory Board for Medical Specialties.

D. Official recognition of the board is indicated by listing the specialty in the "Essentials for Approved Examining Boards in Specialties" and indicating certified specialists with an appropriate symbol in the Directory of the American Medical Association.

RESIDENCIES IN THE SPECIALTIES

Procedures for considering an institution for approval of a residency for training in a recognized specialty are as follows:

A. The institution should make application to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

B. The Council conducts a survey of the institution to determine whether the residency complies with the Council's "Essentials of Approved Residencies and Fellowships."

C. The Council prepares a report on its findings and conclusions which is submitted to the specialty board concerned for its recommendations.

D. Approval may then be granted by the Council.

WITHDRAWAL OF APPROVAL

On conference with the respective specialty boards or with the Advisory Board for Medical Specialties, the recognition extended by the Council on Medical Education and Hospitals of the American Medical Association to holders of certificates from special examining boards, or that granted to a specialty board, may be withdrawn. Approval may likewise be withdrawn from institutions offering residencies when resurveys by the Council reveal a failure of the institution to maintain a satisfactory educational program.

Each specialty board publishes a booklet containing information regarding its organization, personnel, purposes and requirements for certification. A statement of these requirements for each board was published in the Educational Number of THE JOURNAL in 1942.[4] Only a few minor changes have been made by some of the boards since these regulations were published in 1942.

In 1946 three boards certified candidates in subspecialties. The American Board of Internal Medicine certified in allergy, cardiovascular disease, gastroenterology and pulmonary diseases (formerly called tuberculosis). Similarly the American Board of Surgery certified specialists in proctology. The American Board of Pediatrics has developed procedures for certifying pediatricians in allergy and certified five physicians to date. Regular board certification is a prerequisite for certification in the subspecialty. This function of these boards in internal medicine, surgery and pediatrics certifying specialists in the subspecialties is also approved by the Council.

There has been some misunderstanding regarding the status of the so-called subspecialties of proctology (in surgery), cardiovascular diseases, gastroenterology, tuberculosis (in medicine) and allergy (in medicine and pediatrics). These subspecialties are fully recognized by the Council on Medical Education and Hospitals of the American Medical Association. As such they are appropriate fields in which to organize residency training when the facilities warrant. Approved training programs will be listed under these headings in the Council's official list of approved residencies whenever the subspecialty board so desires.

The majority of the boards grant some credit for military service. The policies adopted by the boards vary. One board grants an indefinite amount of credit, to be determined by an evaluation of the experience of individual applicants. The board in surgery grants full credit for work done in the surgical division of a regularly constituted army or navy hospital. Most boards limit the credit allowed to one year of training and/or one year of experience. The special provisions for military credit made by each board were published in the 1943 Educational Number of THE JOURNAL.[5] Medical officers who did not keep an account of work done in military service in the booklet entitled "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards" provided by the boards may now submit a duly certified statement of their military service as a part of the credentials to be submitted on application for the certification examination.

Because of the large number of applications for approval of residency training programs submitted by hospitals developing these programs in response to the increased demand for training by returning medical officers, the Council on Medical Education and Hospitals of the American Medical Association in February 1946 approved a plan for the temporary approval of residencies. This plan was developed in collaboration with the Advisory Board for Medical Specialties through its executive committee. The efforts of the Council, hospitals and medical schools have resulted in providing residency positions in civilian hospitals for 10,422 physicians as of March 1, 1947 as compared with 5,256 in 1941. In the course of the calendar year 1946 there were 511 residency services approved on a temporary basis. Of these services nearly 40 per cent have subsequently been given permanent approval on the basis of surveys of the hospitals providing the residencies. It is anticipated by the Council that the temporary approval of residencies might soon be discontinued.

TABLE 42.—*Specialty Board Credit for Preceptorship Training*

		Preceptors Limitations			
	Credit Awarded	Any Certified Board Member	Other Than Certified Board Member	List of Preceptors Maintained	Maximum Clinical Training Credit
Anesthesiology	Yes	No[2]	Yes (rarely)[2]	No	2 years
Dermatology and syphilology	Yes	No[2]	No	Yes	[5]
Internal medicine	No[1]	....	....	...	....
Neurologic surgery	Yes	No[2]	No	No	No limit set
Obstetrics and gynecology	Yes	Yes	Yes[2]	No	Aver. 6 mo. per year of service
Ophthalmology	Yes	No[2]	Yes[2]	No	No limit set
Orthopedic surgery	Yes	Yes	No	No	3 years
Otolaryngology	Yes	Yes	Yes[2]	No	5 years[6]
Pathology	No	....	....	...	....
Pediatrics	No	....	....	...	....
Plastic surgery	Yes	Yes	No	No	Full credit
Psychiatry and neurology	No	....	....	...	....
Radiology	No	....	....	...	....
Surgery	Yes	Yes[3]	No	No	2 years
Urology	Yes	Yes[4]	No	No	3 years

1. All preceptorships now recognized by the board to be discontinued July 1, 1947. No new preceptors to be appointed.
2. Facilities and teacher qualifications must be approved by board.
3. Institution must be approved for graduate training.
4. Board member must certify training facilities are adequate and must certify at end of training period that candidate has had adequate training.
5. Two years, half time, one half of each day being spent in an approved institution; or one year full time in the preceptor's office in localities where approved institutions are not available.
6. Six years required after July 1950.

TABLE 43.—*Annual Specialty Board Certifications Since 1940*

Year (Ended March)	Number of Boards in Existence	Number Certified That Year	Accumulated Totals
1940	14	.....	15,853
1941	15	2,085	17,938
1942	15	1,756	19,694
1943	15	2,172	21,866
1944	15	1,578	23,444
1945	15	1,308	24,752
1946	15	1,320	26,072
1947	15	2,404	28,476

Eleven boards recognize training with a qualified preceptor as a substitute for special clinical training. The policies of the boards toward the acceptance of such training are briefly outlined in table 42. The time credit allowed varies but in all instances is decided on an individual basis. The individual facilities and teacher qualifications of the preceptor must be approved by the respective board. This type of training is not accepted by four boards. The American Board of

---

[4] J. A. M. A. **119:** 1345 (Aug. 15) 1942.
[5] J. A. M. A. **122:** 1085 (Aug. 14) 1943.

Internal Medicine has recently ruled that all preceptorships will be discontinued as of July 1, 1947 and no new preceptors will be appointed. Only four of the boards will give consideration to preceptor training carried out under a qualified specialist who is not himself certified by the appropriate board. One board maintains a list of preceptors.

Table 43 gives the annual number of specialists certified by all boards for the past seven years and the accumulated totals. The largest number (2,404) obtained certificates in the period from March 1, 1946 to March 1, 1947. Of all those physicians now certified, 12,623 (44 per cent) received their specialty credentials in the past seven years.

A list of the specialty boards, their officers and the number of certificates awarded prior to March 1, 1946 and the number certified to March 1, 1947 respectively appear in table 44. On March 1, 1946 there were 26,072 physicians certified by the fifteen boards, and in the year ended March 1, 1947, 2,404 were certified. Up to this date a total of 28,476 had been certified.

Included in the 28,476 certified in major specialties are 882 who were also certified in subspecialties by the boards in internal medicine, pediatrics and surgery as follows:

Internal Medicine	
Allergy	95
Cardiovascular Disease	361
Gastroenterology	183
Pulmonary Diseases (formerly called "Tuberculosis")	163
Pediatrics	
Allergy	5
Surgery	
Proctology	75
Total	882

The greatest number in any one specialty were certified in internal medicine: 4,449 to March 1, 1947. Of this number 543 were certified in the past year. During the past year also 445 were certified by the board in psychiatry and neurology, bringing the total certified by this board to 2,438. Significant increases in the last year were also noted in surgery (284), obstetrics and gynecology (172), radiology (168) and pediatrics (152). Neurological surgery certified twenty and plastic surgery eight. The oldest board in existence, ophthalmology (organized in 1917) certified 74 last year, bringing the total certified to date as 2,564. Heretofore the greatest number certified in any one specialty was in otolaryngology. In this specialty 3,988 have received the board's certificate since its organization in 1924.

A key number has been assigned to each approved board, such as A.B. 1, and the biographic records of physicians published in the American Medical Directory includes by these means reference to those certified.

The second volume of the "Directory of Medical Specialists," compiled by the Advisory Board for Medical Specialties, was published in 1946. This directory coordinates the work of the several specialty boards by combining in one volume the details of the activities of all boards with lists of their diplomates, including biographic information and data pertaining to the graduate educational background of each of the specialists certified by an American board. This volume lists 24,028 specialists certified prior to November 1945 by the fifteen American Boards and represents only those living at the time of publication but includes many who have retired from active practice.

SATURDAY, MAY 17, 1947

MEDICAL LICENSURE

When Dr. Arthur Dean Bevan retired from the chairmanship of the Council on Medical Education and Hospitals of the American Medical Association more than twenty years ago he wisely emphasized that the accomplishments of the Council depended in large measure on its cooperation with other agencies and organizations that seek to improve medical education and the quality of medical care. The collaboration of the Council with the medical licensing agencies is typical of this philosophy. The publication of licensure statistics has figured prominently in the improvement of medical education in this country for over four decades. In this issue are presented the data on licensure for the year 1946, made possible by the conscientious reporting of examination and reciprocity actions of every governmental unit of the United States, its territories and its possessions, as well as the boards of examiners in the basic medical sciences, the National Board of Medical Examiners and each examining board in the medical specialties.

The candidates for licensure in the United States whose examination results are reported represented sixty-nine approved medical schools in the United States, nine approved medical schools of Canada, eighty-six faculties of medicine and four licensing corporations of other countries, eight medical schools now extinct, six unapproved institutions and seven colleges of osteopathy.

During the year 1946 there were 16,129 licenses issued, 6,559 after examination and 9,570 by reciprocity and endorsement. These figures represent an unprecedented increase over all previous years in both groups. Of those licensed, 6,959 represented real additions to the profession in this country, since many previously held licenses elsewhere. The number of physicians lost by death and emigration was 3,358, so that in 1946 the physician population in the United States was increased by 3,601.

Never before have there been anywhere near as many licenses issued by reciprocity and endorsement as in the past year. This is probably because unprecedented numbers of physicians are seeking new locations after the disrupting influence of the war.

Failures of candidates in various categories in examinations given by state licensing boards followed the familiar pattern. Only 3.1 per cent of graduates of existing approved medical schools failed. On the other hand, 41.6 per cent of those from unapproved schools failed and 55.5 per cent of the graduates of schools outside the United States and Canada did not pass.

Reprints of this report and of separate tables, in demand from numerous sources, will be available on request as one of the services rendered by the Council in replying to the thousands of annual requests for information on licensure.

METOPON HYDROCHLORIDE

In 1929 with funds provided by the Rockefeller Foundation the National Research Council, through its Committee on Drug Addiction, established a coordinated program to study drug addiction and to search for a nonaddicting pain-relieving drug comparable to morphine. The principal participating organizations were the Universities of Virginia and Michigan, the United States Public Health Service, the Treasury Department's Bureau of Narcotics and the health department of the state of Massachusetts. These agencies brought together chemical, pharmacologic and clinical facilities for the purposes of the study. Now a new morphine derivative—metopon hydrochloride (methyldihydromorphinone hydrochloride), one of many compounds made and studied in this coordinated effort—will soon be available.

Chemically metopon is a morphine derivative; pharmacologically it is qualitatively like morphine even to the properties of tolerance and addiction liability. Chemically metopon differs from morphine in three particulars: one double bond of the phenanthrene nucleus has been reduced by hydrogenation, the alcoholic hydroxyl has been replaced by oxygen and a new substituent, a methyl group, has been attached to the phenanthrene nucleus. Studies made thus far indicate that pharmacologically metopon differs from morphine quantitatively in all its important actions—its analgesic effectiveness is at least double and its duration of action is about equal to that of morphine; it is nearly devoid of emetic action; tolerance to it appears to develop more slowly and to disappear more quickly and physical dependence builds up more slowly than with morphine; therapeutic analgesic doses produce little or no respiratory depression and much less mental dulness than does morphine, and it is relatively highly effective by oral administration.

In addition to animal experiments these differences have been established by extensive employment of the drug in two types of patients: people addicted to morphine and others (patients dying of cancer) needing prolonged relief from pain but without previous experience with opiates. In morphine addicts metopon appears only partially to prevent the impending signs of physical and psychic dependence. When the drug is administered orally to patients with incurable cancer it gives adequate relief from pain with little mental dulling, without nausea or vomiting and with slow development of tolerance and dependence.

The high analgesic effectiveness of oral doses (with the elimination of the disadvantage to the patient of hypodermic injection), the absence of nausea and vomiting even in patients who vomit with morphine or other derivatives, the absence of mental dulness and the slow development of tolerance and dependence place metopon in a class by itself for the treatment of the chronic suffering of cancer. It is for that purpose exclusively that it is being manufactured and marketed.

Metopon will be available only in capsule form for oral administration. The capsules will be put up in bottles of 100, and each capsule will contain 3 mg. of metopon hydrochloride. They can be obtained by physicians only from Sharp & Dohme or Parke, Davis & Co. on a regular official narcotic order form, which must be accompanied with a signed statement supplying information as to the number of patients to be treated and the diagnosis on each. The drug will be distributed for no other purpose than oral administration for chronic relief of pain in cases of cancer.

The dose of metopon hydrochloride is 6 to 9 mg. (two or three capsules), to be repeated only on recurrence of pain, avoiding regular by-the-clock administration. As with morphine, the dose should be kept at the lowest level compatible with adequate relief of pain. Therefore, administration should be started with two capsules per dose, increasing to three only if the analgesic effect is insufficient.

Tolerance to any narcotic drug develops more rapidly with excessive dosage and under regular by-the-clock administration. Also, as a rule, the pain of cancer varies widely in intensity from time to time. Pain, therefore, should be the only guide to time of administration and level of dosage. Tolerance to metopon hydrochloride develops slowly; it can be delayed or interrupted entirely by withholding the drug occasionally for twelve hours or for as much of that period as the incidence of pain will permit.

To each physician will be sent a record card for each patient to whom metopon hydrochloride is to be administered. He will be requested to fill out these cards and return them in the addressed return envelop. He must furnish this record of his patient and his use of metopon hydrochloride if he wishes to repeat his order for the drug. The principal object of this detailed report is to check the satisfactoriness of metopon hydrochloride administration in general practice. The physician's cooperation in making it as complete as possible is earnestly solicited.

The limited use of metopon hydrochloride as here described has been recommended by the Drug Addiction Committee of the National Research Council; this committee, with the cooperation of the American Cancer Society, will supervise the distribution of the drug. The committee is composed of William Charles White, Chairman, Washington, D. C.; H. J. Anslinger, Commissioner of Narcotics, United States Treasury Department, Washington, D. C.; Lyndon F. Small, National Institute of Health, Washington, D. C., and Nathan B. Eddy, National Institute of Health, Washington, D. C.[1]

THE TEACHING OF NUTRITION—IV

Until recently consideration of dietary problems in relation to surgical patients has been of relatively small importance. Quantitative rather than qualitative problems were of chief concern. When to give food to patients after gastric operations or peritonitis was the type of nutritional problem that interested the surgeon. A real knowledge of dietetics was not needed to solve such problems, if they were solved. Actually, true quantitative thinking concerning the problem was seldom if ever done. Measurements were not used, but expressions such as "give the patient a 'light' soft solid diet." Medical consultants were asked for advice when any problems more complicated than these appeared.

Recently, however, nutrition has been found so important in the recovery of patients with various "surgical" diseases that the surgeon himself has been forced to pay more and more attention to the diets and dietary supplements, such as vitamins, that are given his patients. This is especially true since intravenous alimentation with protein digests, plasma and vitamins has been made available to complicate the former rather simple routines for early postoperative care that existed ten years ago. Then the only fluids given intravenously were saline solution, glucose and whole blood.

Infections and injuries (and the latter include major surgical operations) produce rapid wastage of protein tissues and of stores of vitamins and minerals. A fair percentage of the patients also suffer from deficiencies of protein and various vitamins and minerals before their injury. Severe infection or injury may result in early nutritional disturbance in the healthy patient, while slight infection or injury may have the same result in the man already depleted.

So far as is known, formal, systematic teaching of the nutrition of surgical patients is done in few medical schools or hospitals. Although it is not easy to find the time for anything new in any curriculum, the small amount of time necessary should be found.

---

[1] Queries and comments on metopon may be directed to Dr. Eddy, who will answer them for the committee.

Formal lectures can do little more than create an interest in the subject. Detailed work on individual patients with responsibility for diets is needed, together with close observation of the patient's response to the food and other nutrients ordered. Exercises should be held with small sections of students who are working actively and constantly with the patients. Besides the instructor, residents, interns, students and, above all, a trained dietitian should make up the study group. First, the members of the group must think in terms of the amounts of protein, vitamins, minerals and calories their patient needs to maintain his strength and to replace at the optimum rate any past deficits. Second, they must learn to think of food in terms of the carbohydrate, protein, fat, vitamins and minerals the food contains and the number of calories it furnishes. Third, they must estimate, with the aid of the dietitian, how closely it is practical for them to try to balance intake against probable utilization and need.

The ground that could be covered by such a study group is much greater than the time that could possibly be allotted to it. However, some of the most important subjects that should be kept in mind are the relationships of protein, vitamins and anemia to surgical shock; the loss of protein and sodium chloride in pus and other excretions; loss of weight after surgery and its prevention; the relative importance of technical errors, distention, plasma protein deficiency and ascorbic acid deficiency in wound disruption or in poor wound healing; differences between the amounts and kinds of food ordered and the foods presented to the patients; differences between the amounts and kind of food presented to the patients and the foods eaten; differences between the amounts and kinds of food eaten and the foods actually absorbed from the intestine; the food values in the various diets consumed and how they may be calculated; how a diet containing 400 Gm. of protein and furnishing 4,000 calories can be given to a very sick patient, and what vitamins, minerals, protein and calories are needed each day by the patient with chronic ulcerative colitis or with an extensive unhealed burn at the end of three weeks.

Suggested answers to these questions may be easily available, but how often are the questions asked or discussed in active surgical services?

Such a study group could pay some attention to the costs of the various diets and supplements ordered. In general all doctors try to find ways and means of securing for their patients any necessary treatment regardless of cost. However, especially in nutrition, there are times when less costly materials are as good as or better than costly ones. For instance, if plasma is used intravenously purely to furnish protein, it costs at least $1 per gram of protein. Suitable digests for intravenous use furnish protein equivalent at less than 10 cents per gram and are often safer to give to the depleted patient because they do not contain the large amount of sodium that plasma does. When it comes to oral feeding hamburger steak at 40 cents a pound furnishes protein at one-half cent a gram. But skim milk powder at $16 a hundred pounds furnishes protein at 1 mill per gram, and with it one gets a large quantity of sugar and certain vitamins free. When a patient is seriously depleted of protein and has a deficit of many kilograms, plasma is useless for intravenous feeding and skim milk and skim milk powder are better than steak for oral feeding! This is true not only because of the price but also because so much more can be taken by the patient in a given time. These are some of the most important elementary lessons of nutrition that surgeons should study and learn.

Current Comment

GAMMA GLOBULIN VS. THE COMMON COLD

Clinical evidence that human serum globulin contains antibodies against common respiratory diseases presumably caused by unknown pneumotropic viruses is offered by Adams and Smith[1] of the Department of Pediatrics, University of Minnesota. Medical students were selected for prophylactic tests. A careful history of their past experiences with acute respiratory infections was obtained. From these data they were divided into groups based on the previous frequency of the disease. One half of each group was selected for experimental study. In October an initial dose of 6 cc. of concentrated gamma globulin solution was administered intramuscularly to each student of the experimental group. Thereafter 4 cc. of the same solution was given at monthly intervals, most of the students receiving a total of 30 cc. in seven inoculations. The occurrence and severity of attacks of respiratory disease were determined at frequent intervals for each group. In the experimental groups, 77 episodes of acute respiratory disease were recorded during the academic year. There were 132 episodes in the nontreated group. In the experimental groups the diseases were classified as severe in 10 instances, moderate in 17 and mild in 49 cases. The previous season record of this group showed 28 severe attacks, 38 moderate and 46 mild. In the nontreated group the number and severity of the attacks were identical with those of the previous year. From these data the conclusions are that human gamma serum globulin given in the arbitrarily selected doses reduces the incidence of attacks of acute respiratory disease by about 40 per cent, with a parallel reduction in the severity of individual cases. Whether or not the effective antibodies are specific or nonspecific for the corresponding viruses has not yet been determined. The presence of nonspecific virus inactivating substances in certain Brazilian species of marsupials and rodents has been recently reported by Koprowski[2] of the Rockefeller Foundation.

ORGANIZATION SECTION

World Medical Association

(NOTE.—*Following is a report by two members of the Board of Trustees covering recent attendance of a session of the World Medical Association.*—ED.)

The World Medical Association was proposed in September 1946 at a conference in London. It is the successor of the Association Professionelle Internationale des Médecins.

The purpose of the organization is to foster close relationships among the national medical associations of the world.

A second conference was held in London in November 1946, at which time a tentative draft of a constitution and by-laws was drawn up. An organizing committee of ten was appointed, comprising representatives from Belgium, Canada, Czechoslovakia, France, Great Britain, Egypt, Spain, Sweden, Switzerland and the United States. Dr. T. C. Routley of Canada was elected chairman of the organizing committee, and a joint secretariat was appointed, consisting of the secretary of the British Medical Association, Dr. Charles Hill, and the secretary of the French Medical Association, Dr. P. Cibrie. Dr. O. Leuch of Switzerland was designated treasurer.

The tentative draft of the constitution and by-laws was circulated among the members of the organizing committee for study and comment. It served as the basis of the agenda for the two day meeting held in London at the British Medical Association House on April 14 and 15, 1947.

At this meeting a final draft of the constitution and by-laws was agreed on, and this is to be submitted to the first plenary session of the association for ratification. This session will be held in Paris Sept. 16 to 20, 1947.

The object of the association, in pursuit of which it shall use every means available to it, are:

1. To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available.
2. To maintain the honor and protect the interests of the medical profession.
3. To study and report on the professional problems which confront the medical profession in the different countries.
4. To organize an exchange of information on matters of interest to the medical profession.
5. To establish relations with and to present the views of the medical profession to the World Health Organization, UNESCO and other appropriate bodies.
6. To assist all peoples of the world to attain the highest possible level of health.

The original draft had provided that the association could pass resolutions and make recommendations relative to the medical care situation in any country. The American representatives objected strenuously to this and it was deleted. We made no objections to factual reports but felt that no outside agency should make recommendations relative to our internal situation or the internal situation of any other country.

It was decided that the association should consist of a general assembly comprising two delegates from each participating association. Each association may also send observers in addition to the delegates. This general assembly shall have general control over the policy and affairs of the association. The officers are to be a president, a president-elect, a secretariat (which, as soon as possible, will consist of a single secretary on a paid full time basis with the necessary assistance) and a treasurer. The general assembly will meet once a year and, so far as possible, in a different country each year. The president-elect will be chosen from among the outstanding physicians of the country in which the next meeting is to be held.

A council is to be established, which will consist of the president, the president-elect, the treasurer and nine elective members, three of whom are to be elected each year for three years. The first year three are to be elected for three years, three for two years and three for one year. The council will meet just before and just after the general assembly and once in between the meetings of the assembly. It will carry out the resolutions of the assembly and administer its affairs in conformity with the constitution and by-laws. The council shall elect its own chairman.

English and French are the official languages, and translation is provided.

A journal is to be published at intervals yet to be decided. Articles may be published in either English or French, but official notices are to be published in both languages. The council is to nominate an editor of the journal, to be elected by the general assembly.

The constitution can be amended only after nine months' notice and by a two-thirds vote. The by-laws and resolutions pertaining to finance may be amended after four months' notice and by a majority vote. Referenda of the member associations are provided for on important changes of policy.

The dues of the association depend in part on the size of the member association. Each member association is to pay 10 Swiss centimes per member, but each association will pay at least 1,000 Swiss francs and no member association shall pay more than 10,000 Swiss francs. The council will have authority to reduce the assessment in appropriate circumstances.

This caused considerable discussion, as some members suggested a flat rate per member. This was objected to by us, as it would have resulted in our paying more than half of all the assessments. It was pointed out that the American Medical Association, although comprising over 130,000 members, receives no dues from its members and receives only the subscriptions for the publications subscribed for by its Fellows.

The aforementioned arrangement was then agreed on as a compromise.

There are now fifty-nine national medical organizations in the world. The national associations of the following countries are the founder associations of the World Medical Association: Austria, Australia, Belgium, Canada, Chile, Czechoslovakia, Denmark, Egypt, Eire, Finland, France, Great Britain, Greece, Hungary, Iceland, Iraq, Luxembourg, the Netherlands, New Zealand, Norway, Persia, Poland, Portugal, Spain, Sweden, South Africa, Switzerland, Turkey and the United States.

This new organization has great potentialities. It will afford a mode of rapprochement among the doctors of the world. With the present chaotic state of international affairs, it would seem that the doctors should have no difficulty in getting together as they have one common aim, expressed in the final item of the object of the association, "to assist all peoples of the world to attain the highest possible level of health."

After the draft of the constitution and by-laws had been completed, a tentative budget was authorized.

Dr. T. C. Routley was designated to represent the World Medical Association at the Centenary of the American Medical Association.

Dr. Routley reported that tentative arrangements had been made to distribute a book on nutrition, prepared by the American Medical Association, the Canadian Medical Association and the National Research Council of the United States, to all doctors of the world. The expense of printing is to be defrayed by the Mead Johnson Company.

A draft of a questionnaire to be sent to all national medical associations was approved and it has been sent out. The questionnaire is entitled "Enquiry into the Present Position of the Medical Profession and Its Relation to the State."

On the evening of April 14 the British Medical Association gave a dinner to the committee. It was presided over by Sir Hugh Lett, president of the British Medical Association.

Later in the week we were both privileged to inspect the work of two of the largest hospitals in London.

On the evening of April 17 we were entertained at the Athenaeum Club by Dr. Hugh Clegg, editor of the *British Medical Journal.* We had an opportunity to discuss the new British National Health Service Act with Sir Wilson Jameson, chief medical officer of the British Health Ministry, and Sir Allan Daly, chief medical officer of the London Hospital Council.

Respectfully submitted,

LOUIS H. BAUER, M.D.
ELMER L. HENDERSON, M.D.

Council on Medical Service

CASH SICKNESS BENEFITS FOR RAILROAD WORKERS

A cash sickness benefit system for railroad workers will begin operating throughout the nation on July 1. These benefits were added under the 1946 amendments to the Railroad Unemployment Insurance Act and provide partial compensation for wage loss due to disability on the same basis as that due to unemployment. The system will be administered by the Railroad Retirement Board, which administers the Railroad Unemployment Insurance Act.

All disabilities which prevent railroad employees from working, regardless of how or where they occur, are covered under the program. In the first year of operations, about 300,000 of the 2,075,000 railroad workers qualified are expected to receive benefits, and the total amount of benefits is expected to reach $36,000,000.

A physician's statement of sickness will be required before claims can be paid. It is believed that the program will require about 650,000 medical examinations a year. Employees are free to choose their own doctors, and any physician to whom an employee goes for examination or treatment may supply the information required as initial proof of an employee's claim.

The forms on which medical information will be requested from a physician are the "Statement of Sickness" and the "Supplemental Doctor's Statement." The first mentioned form is intended primarily to obtain information at the beginning of each illness, and the second is intended to obtain additional information only when such information is needed later on in the same illness. The statements are designed to furnish, as simply and as conveniently as possible for the physician, the minimum information required for board purposes.

The "Statement of Sickness" on which the medical evidence is to be furnished must be mailed to the appropriate office of the Railroad Retirement Board within seven days after the first day claimed as a day of sickness, or the employee may lose part of his benefits. Claims for succeeding fourteen day periods may be allowed for a predetermined period as indicated by the medical evidence on the doctor's initial statement, but in continuing illnesses supplemental information about the patient's illness may also be requested from the physician.

Claims will be filed and adjudicated in the regional offices of the Railroad Retirement Board. These offices are located in Atlanta, New York, Cleveland, Chicago, Dallas, Kansas City, Minneapolis, Denver and San Francisco and serve the adjoining territories. Each will have a physician who will act as a medical consultant. Additional information about the program may be obtained from any of the aforementioned offices.

Washington Letter

(From a Special Correspondent)

May 12, 1947.

Presidential Physician Reports Mr. Truman in Best of Health

Brig. Gen. Wallace Graham, presidential physician, announced that President Truman was in good health on his sixty-third birthday, May 8, although weighing 10 pounds more than he did when he took office. Mr. Truman rises around 5:30 a. m. daily and frequently takes long walks before breakfast. He usually naps for twenty or thirty minutes after luncheon and takes a plunge in the White House pool three times a week.

Bradley Pledges Battle for Veterans Administration Medical Program

Gen. Omar N. Bradley, Veterans Administrator, told his top lieutenants that he will cooperate with Congress in effecting economies but will oppose reductions that will mean a "waste of human resources." He declared that in no case would he permit a reduction in the quality of the Veterans Administration medical program, which he said had "advanced until today it ranks as the outstanding medical program in the world." Among the agency's accomplishments for the past twenty months he listed discharge of 685,000 patients from Veterans Administration hospitals, doubling rate of hospital patient turnover, addition of 23,000 hospital beds, 8,000,000 outpatient examinations, 6,000,000 outpatient treatments and the opening of 152 outpatient clinics and 31 clinics for mental hygiene.

War Department to Stress Medical Research

The War Department has announced that it will continue its program of military medicine research. Fundamental research will be vigorously continued in the field of chemistry, physiology, pathology and psychology in relation to extremely low temperatures. Development of prosthetic devices, including sensory devices, will be continued in conjunction with the National Research Council and the Veterans Administration. Research in the field of nutritonal, physiologic and psychologic studies of personnel in relation to environment will be continued. Research and collection of data in the field of pathology will be continued by the Army Institute of Pathology. Research will be continued in the field of preventive medicine, i. e. immunology, sanitation, malaria control, venereal disease control, insect and rodent control and respiratory and intestinal disease control methods. Projects will be continued in the broad field of medical and surgical practice, particularly for the development and study of new treatment methods, new therapeutic agents, traumatic surgery, chemotherapy and the treatment of shock. A program in wound ballistics will be carried out in cooperation with the Medical Department, the Ordnance Department and the Chemical Corps. Studies will be carried out to include new methods for use of present antibiotic agents as well as the development of entirely new agents. Fundamental research into the causes and prevention of psychoneurosis will be carried on. Research must be continued into special diseases not covered in the category of medical and surgical practice.

Bureau of Standards Builds Apparatus to Study Atomic Rays

The National Bureau of Standards announced that its scientists have built a "beta-ray spectrometer" to be used in resarch on about 400 radioactive isotopes. The equipment is designed for study of beta particles and gamma rays, some of which are poisonous to certain tissues, while others are said to be usable in both medical treatments and x-ray examination.

Federation of American Scientists

Dr. Robert Marshak, Rochester University physicist, was elected chairman of the Federation of American Scientists. Formerly with the Los Alamos, N. M., laboratory of the atomic bomb project, Dr. Marshak said that the federation would continue its fight for world control of atomic energy under international law and scientific freedom.

Bureau of Information

LOCATION OF PHYSICIANS

Virginia Shuler
Chicago

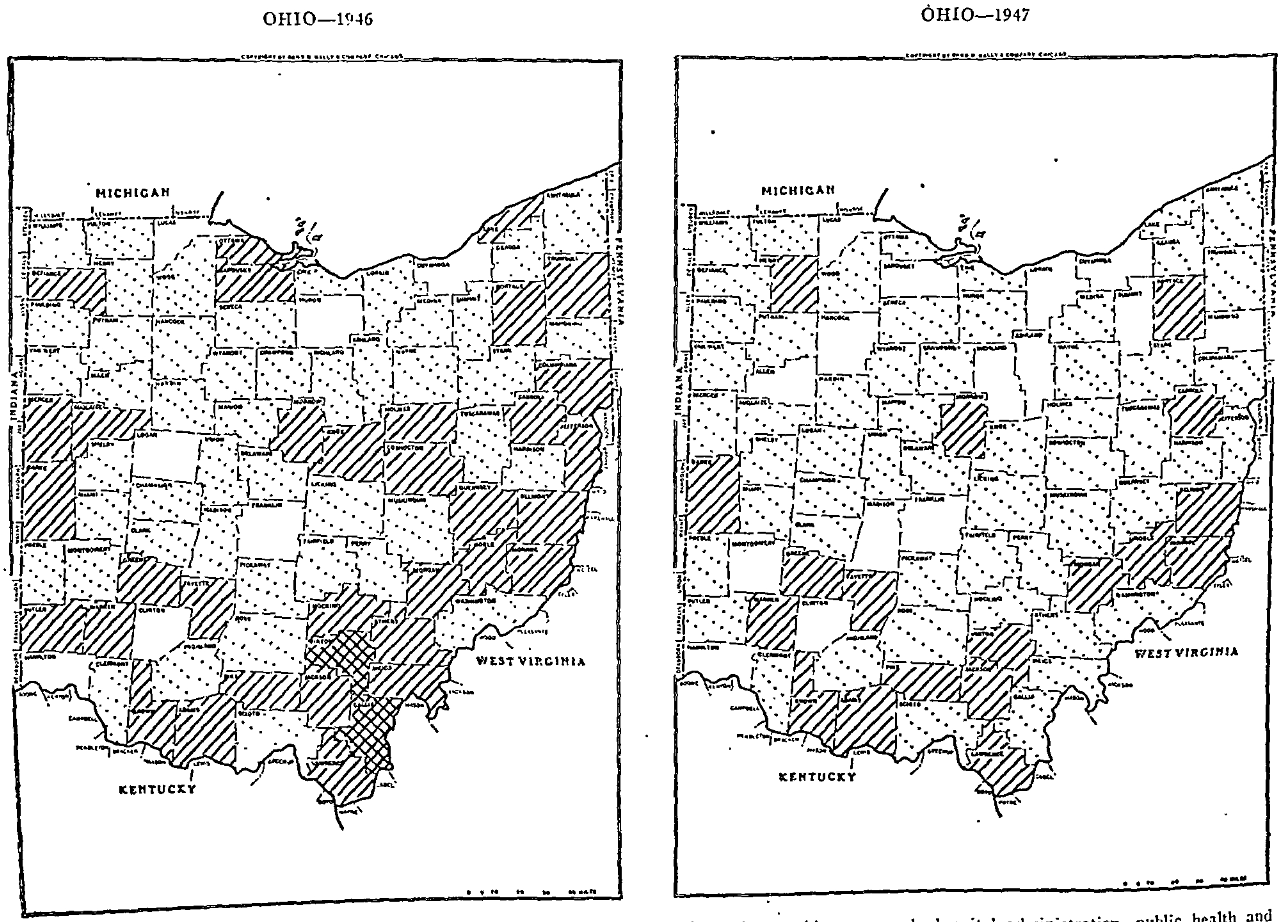
Demobilization is not completely over. Many young physicians are still in the armed forces, and a large proportion of the resident physicians doing postgraduate work in hospitals are men who served in World War II. According to the Directory Department of the American Medical Association, approximately five thousand physicians have not yet decided on a permanent location.

Already the Bureau of Information is sensing the trend of returned medical officers to move away from their recent venture in city practice to accept the opportunities of more active practice in smaller communities. From studies of physician distribution the general picture for location of physicians during the year following V-J day shows an adequate supply of physicians in most of the states but reflects a need for a more coordinated system of medical service in many of the rural areas.

Leaders of the medical profession interested in better rural medical service are working with the farm organizations to outline a program of activity to develop in rural areas an appreciation of modern medical service and the responsibility of the community in planning a health program that will make the country physician a working partner toward decentralization of medical care from urban or large trade centers to the more rural sections of the population. The medical profession and the farm groups want to make rural medical service more adequate not only to the farmer but also to those who extend this service to the farmer.

Dr. F. S. Crockett, Chairman of the Committee on Rural Medical Service of the American Medical Association, has recently announced that the Farm Bureau, the Farmers Union, the Cooperative Milk Producers' Federation and the Grange have each appointed two of their members to act in an advisory capacity to the Committee on Rural Medical Service of the American Medical Association. This committee will hold a meeting soon to outline and develop an active program for regional and local rural representatives. Thomas A. Hendricks, Secretary of the Council on Medical Service, is working out a plan with the Committee on Rural Medical Service to coordinate the Council's and the Committee's regional meetings in order to develop through workshop conferences the most adequate extension of medical service to all areas.

In December 1946 the Bureau of Information began a survey through the local medical societies to determine the conditions and distribution of medical care in the rural areas of the country. Through the cooperation of the secretaries of the state and county medical societies, listings of areas which have requested physicians are available to help the doctor in selecting an area in which to establish his medical practice.



OHIO—1946

OHIO—1947

Population, based on 1943 estimated Census figures, per active physician (excludes teaching, research, hospital administration, public health and state hospitals) by county.

Key: Physician-population ratio by county: plain area 1-999, dotted area 1,000-1,499, striped area 1,500-2,999, checked area 3,000 and over, solid black area no doctor.

This is the first of a series of charts showing the trend in locations of physicians from April 1946 to January 1947.

"Conditions in Ohio are still somewhat abnormal. A considerable number of men returning from the service who would ordinarily have gone into private practice are at present engaged in postgraduate work. During the past year we have been successful in a good many instances in locating men in certain communities; nevertheless, we still have a rather extensive list of small areas needing a physician or where the population would like to have a physician or another physician. We are doing our best to get this information in the hands of those seeking locations, including Ohio physicians as well as physicians in other states. In my opinion this is a problem which will not be corrected in the immediate future and perhaps will take years to work out. Efforts are being made by this association, in cooperation with Ohio's three medical schools, to impress on graduates the need for physicians in rural areas and the advantages offered by such areas. On the other hand, we are endeavoring to list the so-called disadvantages of rural practice so that efforts can be made in an organized way to correct situations which cause these disadvantages. Until some of these situations are corrected, we cannot expect a much larger percentage of new graduates to locate in outlying areas."

Mr. Charles S. Nelson, Executive Secretary,
Ohio State Medical Association,
1005 Hartman Theater Building,
Columbus 15, Ohio.

"With the exception of Lawrenceburg, a city of approximately 5,000 in the southeastern part of our state, all cities of any size in Indiana now have sufficient physicians. Lawrenceburg could use two doctors. The main industry is whisky distilling. Lawrenceburg does not have a hospital, but it is not more than 25 miles from Cincinnati. One of the problems a doctor would face in locating there would be to find a suitable place to live.

"We have approximately twenty-five towns under 1,000 population which could support a physician. Several, namely Moreland, Van Buren and Cayuga, have local committees endeavoring to induce a doctor to locate in their communities. Physicians could make a pretty good living in any of the aforementioned towns.

"I would say that our larger cities, including county seats, all have adequate medical service at the present time."

MR. RAY E. SMITH, Executive Secretary,
Indiana State Medical Association

"During the year 1946 approximately 150 physicians located in rural Missouri for the first time. However, there are still a number of counties in this state which are in need of more physicians. Also during the year 1946 a number of rural communities opened hospitals which were directly responsible for the location of a number of young physicians in those areas. This experience is convincing evidence that where hospital facilities are available the problem of securing physicians is greatly reduced. One or two communities in Missouri have taken the initiative in developing hospital facilities in their communities. They have assisted these physicians in finding suitable living quarters, office space and equipment, and automobile when needed, and through this procedure have obtained the services of needed physicians. During the year 1946 a number of rural communities after careful study voted bonds to provide community hospital facilities. The Missouri State Medical Association has been successful in cooperating with a number of communities in aiding these communities to secure physicians. The state association through its Committee on Rural Medical Service has surveyed the state from the standpoint of medical manpower and has thereby been made cognizant of where physicians are badly needed and has determined for the most part whether communities can or cannot support another physician."

MR. RAYMOND MCINTYRE, Field Secretary,
Missouri State Medical Association,
623 Missouri Building,
St. Louis 3.

Coming Medical Meetings

American Medical Association, Atlantic City, June 9-13. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Aero Medical Association of the United States, Atlantic City, Ritz-Carlton Hotel, June 4-6. Dr. David S. Brachman, 1016 Dime Bldg., Detroit 26, Secretary.

American Association for the Surgery of Trauma, Atlantic City, Hotel Claridge, June 5-7. Dr. Gordon M. Morrison, 520 Commonwealth Ave., Boston 15, Secretary.

American Association for Thoracic Surgery, St. Louis, May 28-30. Dr. Richard H. Meade Jr., 55 E. Washington St., Chicago 2, Secretary.

American Association of Genito-Urinary Surgeons, Absecon, N. J., June 4-6. Dr. Charles C. Higgins, 2020 E. 93d St., Cleveland 6, Secretary

American Association of the History of Medicine, Cleveland, May 25-26. Dr. Howard Dittrick, 2020 E. 93d St., Cleveland 6, Secretary.

American Association on Mental Deficiency, St. Paul, Minn., May 28-31. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American College of Allergists, Atlantic City, Hotel Senator, June 6-8. Dr. Fred W. Wittich, 401 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Chest Physicians, Atlantic City, Ambassador Hotel, June 5-8. Mr. Murray Kornfeld, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Radiology, Atlantic City, Haddon Hall, June 7-8. Mr. Mac F. Cahal, 20 N. Wacker Drive, Chicago 6, Executive Secretary.

American Dermatological Association, Murray Bay, Quebec, Can., June 1-5. Dr. Harry R. Foerster, 208 E. Wisconsin Ave., Milwaukee, Wis., Secretary.

American Diabetes Association, Atlantic City, Chalfonte-Haddon Hall, June 7-8. Dr. Cecil Striker, 1019 Provident Bank Bldg., Cincinnati 2, Secretary.

American Urological Association, Buffalo, N. Y., Hotel Statler, June 30-July 3. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Association for the Study of Internal Secretions, Atlantic City, June 6-7. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Federation of American Societies for Experimental Biology, Chicago, May 18-22. Dr. William H. Chambers, 1300 York Ave., New York 21, Secretary.

Idaho State Medical Association, Sun Valley, June 16-19. Dr. William B. Handford, Caldwell, Secretary.

Maine Medical Association, York Harbor, Marshall House, June 22-24. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Massachusetts Medical Society, Boston, Hotel Statler, May 20-22. Mr. Robert St. B. Boyd, 8 Fenway, Boston 15, Executive Secretary.

Medical Library Association, Cleveland, Wade Park Manor, May 27-29. Miss Heath Babcock, New York State Medical Library, Albany 1, New York, Secretary.

Minnesota State Medical Association, Duluth, June 30-July 2. Dr. B. B. Souster, Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Montana, Medical Association of, Missoula, June 26-28. Dr. H. T. Caraway, 115 N. 28th St., Billings, Secretary.

National Gastroenterological Association, Atlantic City, Hotel Chelsea, June 4-6. Dr. G. Randolph Manning, Room 319, 1819 Broadway, New York, Secretary.

National Tuberculosis Association, San Francisco, June 16-19. Dr. F. D. Hopkins, 1790 Broadway, New York 19, Executive Secretary.

New Hampshire Medical Society, Portsmouth, Hotel Wentworth, June 19-20. Dr. Carleton R. Metcalf, 5 South State Street, Concord, Secretary.

New York State Association of Public Health Laboratories, Syracuse, May 27. Miss Mary B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

North Dakota State Medical Association, Fargo, May 25-27. Dr. L. W. Larson, 221 Fifth St., Bismarck, Secretary.

Society of Surgeons of New Jersey, Atlantic City, Seaview Country Club, May 28. Dr. Walter B. Mount, 21 Plymouth St., Montclair, N. J., Secretary.

South Dakota State Medical Association, Rapid City, May 31-June 3. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

Wyoming State Medical Society, Sheridan, June 23-25. Dr. George E. Baker, 226 E. 2d St., Casper, Secretary.

Official Notes

TRAINS FROM PHILADELPHIA TO ATLANTIC CITY

For the information of persons attending the Centennial Session of the American Medical Association in Atlantic City, June 9-13, the Pennsylvania Railroad will run trains daily leaving Philadelphia for Atlantic City in the forenoon at 7:15, 8:30 and 9:30 Eastern Standard Time. The last train returning to Philadelphia from Atlantic City leaves at 9:30 p. m. Extra cars will be added to these trains during the period of the meeting if the need arises.

Medical Legislation

STATE LEGISLATION

California

Bills Passed.—A. 438, which passed the house April 28, proposes that **no blind person** shall be denied admission into any college or school of chiropractic or denied admission to examination and licensure because of such blindness. S. 1068, which passed the house May 2, proposes to prohibit any person other than a physician and surgeon from making a **postmortem examination** or performing an autopsy. S. 1265, which passed the senate April 28, proposes to exempt from the provisions of the **osteopathic practice act** persons holding drugless practitioner's certificates issued by the board of osteopathic examiners.

Bills Enacted.—A. 796, which has become chapter 125 of the Laws of 1947, amends the health and safety code by authorizing a person, by will, to direct that the whole or **any part of his remains** be given to a teaching institution, university, college or legally licensed hospital, or to the state director of public health. A. 797, which has become chapter 126 of the Laws of 1947, authorizes every person of sound mind over the age of 18 years to dispose, by will, of the whole or **any part of his or her body** to a teaching institution, university, college or legally licensed hospital, either for use as such institution, university, college or hospital may see fit or for use as expressly designated in the will.

Connecticut

Bill Passed.—H 922, which passed the senate April 29, proposes to suspend the operation of the provisions of **the naturopathic practice act** relating to licensure without examination until the adjournment of the 1947 session of the general assembly.

Florida

Bills Enacted.—H. 363 proposes to authorize a court to admit in evidence testimony relative to **the amount of alcohol** in a defendant's blood as shown by a chemical analysis of his breath, urine or other bodily substance whenever a defendant is indicted or tried for being under the influence of intoxicating liquor when he committed reckless homicide or when he drove a vehicle. H. 402 and S. 291 propose to authorize the several cities and towns of the state to levy **license taxes** for the purpose of regulation and revenue on professions H. 440 and S. 394 propose to make it unlawful for **tax collectors** in the several counties to issue state and county occupational licenses to any person applying for license to practice medicine in any of its branches unless and until proof of current qualification and competency, as established by certificate or license issued by the state boards duly constituted and legally authorized to determine qualification and competency, be exhibited at the time of making such application. H. 506 proposes the creation of the **University of Florida School of Medicine**, to be located some place in Hillsborough County. H. 507, *to amend the law relating to* massage, proposes to authorize licentiates thereof to use **electrical apparatus for** the purpose of body massaging, reducing or contouring but prohibits them from engaging in fever therapy. S. 359 proposes that drugs containing **barbituric acid**, declared by the bill to be dangerous, shall not be sold at retail except on written prescription signed by a member of the medical, dental, osteopathic or veterinary profession. Such prescriptions could not be refilled.

Bill Passed.—H. 253, which passed the house April 30, proposes to authorize persons to **donate and give their eyes** for eyesight restoration purposes by last will and testament and authorizes any state, county, district or other public hospital to purchase and provide the necessary facilities and equipment to establish and maintain an eye bank for restoration of sight purposes.

Maryland

Bills Enacted.—H. 256, which has become chapter 716 of the Laws of 1947, appoints the state board of health as an agency to administer a program of noninstitutional services for **mentally ill persons** and to develop a program for extending and improving services to such persons. H. 394, which has become chapter 739 of the Laws of 1947, repeals the existing law regulating the sale of **barbituric acid** and enacts a new law designed for the same purpose. H. 663, which has become chapter 810 of the Laws of 1947, designates the state board of health as the sole agency to represent the state of Maryland in obtaining benefits under the federal hospital survey and construction act and authorizes the governor to appoint an **advisory council on hospital construction.** H. 709, which has become chapter 824 of the Laws of 1947, authorizes the appointment of **a medical advisory board** to which would be referred all cases of persons applying for a driver's license when the granting of a license to such person would be inimical to public safety and welfare because of an existing or suspected mental or physical disability.

Michigan

Bills Introduced.—H. 451 proposes the enactment of a law requiring the licensing, regulation and inspection of hospitals and related institutions and the appointment of an **advisory institutional council.** H. 495 proposes to amend the penal code by making it a misdemeanor for any person to subject a cat, dog or bird or cause it to be subjected to **experimentation or mutilation** while alive or cause it to be sold for the purpose of being subjected to experimentation or mutilation.

New Hampshire

Bill Introduced.—H. 371 was previously reported as proposing the enactment of a **hospital licensing law.** This proposal was amended by house committee on April 29 in part as follows: "No such rules, regulations or standards shall be adopted or enforced which would have the effect of denying a license to a hospital or other institution required to be licensed hereunder, solely by reason of the school or system of practice employed or permitted to be employed by physicians therein; provided that such school or system of practice is recognized by the laws of this state."

New Jersey

Bill Introduced.—A. 314 proposes a licensing law for **nursing homes and hospitals.** An April 14 amendment provided, among other things, that a licensing authority or agency should have no authority "to require any hospital to practice or permit sterilization of human beings, euthanasia, birth control or any other similar practice contrary to the dogmatic or moral beliefs of any well established religious body or denomination."

Bills Enacted.—S. 66, which has become chapter 83 of the Laws of 1947, appoints the state department of institutions and agencies as the agency to receive federal funds to assist in a **state survey of hospitals** and the development of a state program for the construction of additional needed hospital facilities. S. 335, which has become chapter 88 of the Laws of 1947, provides an appropriation to the state department of health for the **purchase of smallpox vaccine** and the distribution thereof free on such terms as the state department of health shall determine.

Oregon

Bill Enacted.—S. 77, which has become chapter 488 of the Laws of 1947, repeals the existing laws requiring the licensing of **maternity hospitals** and certain other types of institutions and sanatoriums and provides a licensing, inspecting and regulating law for all hospitals and related institutions within the state.

Pennsylvania

Bills Introduced.—H. 982 was previously reported as redefining the **practice of chiropody.** A house amendment of April 30 further redefines chiropody as "the diagnosis and treatment of the ailments of the human foot. This shall not confer the right to amputate any part of foot leg or toes or the use of any anesthetic other than local or the treatment of any constitutional disease." H 1317 proposes the creation of a state **board of chiropractic examiners** and defines chiropractic as "a philosophy science and art of things natural a system of locating misaligned or displaced vertebrae of the human spine the procedure preparatory to and the adjustment by hand of such misaligned and misplaced vertebrae and other articulations and tissues of the human body together with the use of x-ray and other scientific instruments of analysis"

Bills Passed.—H. 905, which passed the senate April 28, to amend the law relating to the **practice of osteopathy,** proposes to extend until June 30, 1948 the requirement of a nine months internship prior to examination. H. 917, which passed the senate April 29, to amend the medical practice act, proposes to repeal the 1943 law which reduced for a limited period of time the training period of **medical internship in hospitals.** H. 921, which passed the senate April 29, to amend the medical practice act, proposes to repeal the 1943 law authorizing the issuance of **temporary permits to practice** medicine under certain conditions.

South Carolina

Bill Introduced.—S. 722 proposes to authorize the admissibility in evidence of **microphotographs** or films of any record to the same extent as the originals thereof would have been admitted.

Bill Passed.—H. 24, which passed the house May 1, to amend the marriage law, proposes to require each applicant for a **marriage license** to present a certificate signed by a duly licensed physician of his state certifying that such person is of sound mind and free from venereal disease. H. 761, which passed the senate April 30, appoints a commission to make a full investigation of the practices of the **board of naturopathic examiners** in the state in the matter of issuance of licenses, the examinations and personal qualifications required of applicants to practice naturopathy in the state and the propriety of granting licenses therefor.

Vermont

Bill Enacted.—H. 317, which was approved April 26, provides a **licensing law** for hospitals, sanatoriums, rest homes, nursing homes, homes for the reception of children and related institutions.

GOVERNMENT SERVICES

ARMY

ADDITIONAL TIME FOR MEDICAL PERSONNEL TO SEEK COMMISSIONS

The War Department announces that applications from certain types of medical personnel for Regular Army commissions would be received for an additional three months period beginning May 1 and ending July 31. The original deadline for applications under the Regular Army Integration Program of 1947 had passed on January 31.

Twelve classifications of medical officers and former medical officers will be affected by the new ruling. The classifications are those of bacteriologist, biochemist, parasitologist, serologist, clinical laboratory officer, entomologist, nutrition officer, toxicologist, industrial hygienist, sanitary engineer, clinical psychologist and psychiatric social worker.

The additional application period was announced in an effort to obtain more medical candidates for Regular Army commissions. The first increment of officers brought into the Army in 1947 contained far below the desired proportion of medical officers.

Applicants are limited to medical officers now on active duty and former medical officers of World War II who are or have been qualified in one of the aforenamed specialties. Persons interested were invited to forward applications to the Adjutant General, Attention AGSO-R, Washington 25, D. C., or (in the case of officers now on active duty) through military channels to the Adjutant General.

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration is conducting sales of surplus government property announced by the following regional offices. Physicians who are veterans have certain priorities in the purchase of this government property.

Regional Office, 1409 Second Avenue, Seattle. Sale of operating tables, instrument cabinets, specialists chairs (metal), instrument sterilizers, operating lamps. Sale closes May 26.

Regional Office, 37 Broadway, New York 6. Sale of drugs and pharmaceuticals. Sale closes May 19.

Regional Office, 412 West Market Street, Louisville 2, Ky. Sale of surgical sutures (catgut, braided silk and nylon). Sale closes May 22.

Regional Office, 404 South Wabash Avenue, Chicago 5. Sale of hospital and laboratory equipment and supplies, including rubber tubing (synthetic), instrument trays, instrument tables, hospital beds, perimeters, phorometers, anesthesia apparatus, invalid chairs, litters, chart holders, utensil sterilizers, bedside tables. Sale closes May 26.

Regional Office, 95th and Troost, Kansas City, Mo. Sale of hospital beds, cassettes, oxygen therapy apparatus, bandages, litters, stereoscope (x-ray, large), syringes, surgical instruments, forceps, curets, abdominal retractors, rubber gloves, hot water bags. Sale closes June 4.

Regional Office, 33 Berry Street, San Francisco 7. Sale of drugs and pharmaceuticals. Sale closes May 26.

NAVY

STUDENTS MAY APPLY FOR NAVY COMMISSIONS

The Bureau of Medicine and Surgery, Navy Department, Washington, D. C., announces that students and graduates of accredited medical schools may apply for appointment to commissioned rank in the Navy or the Navy Reserve in the following grades:

1. Assistant Surgeon, U. S. Naval Reserve: All fourth year male students of good scholastic standing enrolled in approved medical schools and male graduates of such schools engaged in intern training or civilian practice (after internship) who meet the prescribed requirements are eligible to apply for appointment to the grade of Assistant Surgeon with the rank of Lieutenant (jg) in the Medical Corps of the U. S. Naval Reserve. Appointment to this status carries no obligation for active naval service except on a purely voluntary basis notwithstanding the extent of any past V-12 training or affiliation. Those former V-12 students who graduated from medical school prior to July 1, 1946 are excluded from this provision and will be required to perform active duty on acceptance of their appointments. Doctors whose age, professional experience and academic seniority justify a more senior grade may make application for appointment to grades above that of Assistant Surgeon.

2. Acting Assistant Surgeon, U. S. Navy (Intern): All fourth year male students of good scholastic standing enrolled in approved medical schools in the United States and Canada who meet prescribed requirements are eligible to apply for appointment to the grade of Acting Assistant Surgeon with the rank of Lieutenant (junior grade) for intern training in a naval hospital. Selected candidates will be issued an appointment and orders to active duty for internship on receipt in the department of a certificate from the dean or registrar of their school to the effect that they have completed their medical school education. Acting Assistant Surgeons are under no obligation to continue in the naval service beyond completion of prescribed course of intern training. The grade of Acting Assistant Surgeon does not exist in the Naval Reserve, nor is intern training in the Navy extended to members of the Medical Corps of the Naval Reserve.

3. Assistant Surgeon, U. S. Navy: Graduates of approved medical schools who have completed intern training in an accredited hospital or who will complete such training within four months of a date set for examination and who meet prescribed requirements are eligible to apply for examination for appointment as Assistant Surgeon with the rank of Lieutenant (junior grade) in the Medical Corps of the Navy. Candidates for this grade are required to appear before boards of medical examiners and supervisory examining boards at a naval hospital on a prescribed date to establish their physical and professional qualifications for appointment. The acceptability of candidates will be finally determined by boards convened in the Navy Department from a review of reports of examination conducted in the field (the next examinations for Assistant Surgeon, U. S. Navy, are scheduled for June 23 to 27, 1947 and thereafter for Oct. 6 to 10, 1947). The grade of Assistant Surgeon represents the lowest permanent grade in the Medical Corps of the Navy and might be classed as the starting point of continuous active service for the physician who elects a career in naval medicine.

4. Ensign, HP (Med), U. S. Naval Reserve: Male students enrolled in or accepted for enrolment in the next convening class of an approved medical school who meet prescribed requirements are eligible for appointment to the probationary rank of Ensign, HP, in the Naval Reserve. Under the current program this appointment carries with it no obligations for active naval service notwithstanding previous V-12 training, nor is the appointee required to accept superseding appointment in the Medical Corps of the Navy or the Naval Reserve on graduation from medical school. This commission is subject to revocation by reason of scholastic failure or for other reason at the discretion of the Secretary of the Navy and in any event becomes subject to revocation on completion of medical school education whether or not the appointee accepts superseding appointment in the Medical Corps of the Navy or the Naval Reserve.

VETERANS ADMINISTRATION

MORE ACCURATE DISABILITY RATINGS

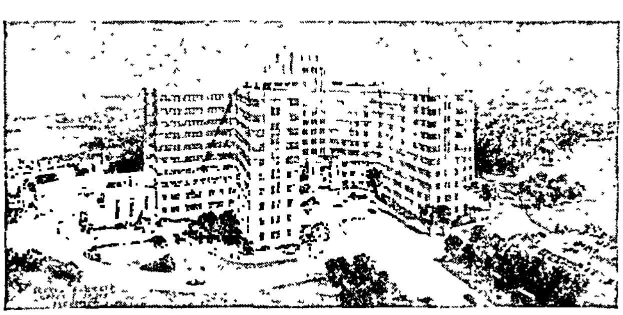
Of the 2,692,000 compensation and pension cases subject to review under the new disability rating schedule approved by the last Congress, the Veterans Administration reviewed 842,000 cases between Aug. 1, 1946 and March 1, 1947. This is 31 per cent of the total. All claims are reviewed automatically and may increas in compensation resulting from the review will be retroactive to April 1, 1946 under the law. The Veterans Administration therefore requests disabled veterans not to make inquiries about their cases while they are pending.

The new schedule, known as the Schedule for Rating Disabilities—1945 Edition, permits the Veterans Administration to make a more accurate evaluation of veterans' disabilities than preceding schedules did; it also provides for new types of combat wounds and tropical diseases encountered by members of the armed forces during World War II.

While the new schedule provides increased ratings for certain types of disabilities and decreases for other types, it does not make any blanket change in ratings. However, the increases far outnumber the decreases. Disability compensation for veterans of both world wars range from $13.80 a month for 10 per cent disability to $138 a month for total disability. Some awards are fixed by law for certain types of disabilities, such as blindness in both eyes, loss of two or more limbs or paraplegia (spinal cord injury). These awards may run as high as $360 a month.

VETERANS' HOSPITAL AT ALBANY, N. Y.

The site of the 1,000 bed veterans' hospital to be constructed at Albany, N. Y., comprises about 25 acres bordered on the southeast by Hackett Boulevard. The structure will be fireproof and ten stories high except for the small center portion, which will be fourteen stories. In addition to the main building there will be quarters for nurses and homes for hospital staff members. Construction of the hospital will be under the direction of the New York District Corps of Engineers, U. S. Army, and construction work is expected to begin this month.



Proposed Veterans' Hospital at Albany, N. Y.

BLINDED VETERANS

Fifteen of the 1,133 veterans who lost their sight in World War II are training to be social workers and eleven others are employed as counselors to the blind; three of the eleven have positions as placement agents, two as industrial counselors, two as supervisors of business enterprises, one as an executive director of the Veterans Administration, one as supervisor of adult visitation, one as an orientation officer and one as an employment interviewer.

The survey made by the Veterans Administration revealed that nearly half of the blind veterans discharged by the Army and Navy up to the end of 1946 were either working or in training; 28 per cent were employed, and of these 197 had full time jobs, 52 part time jobs and 72 were self employed. Another 20 per cent, or 231, were in vocational rehabilitation training, of whom 51 were taking on-the-job training and 180 were in schools and colleges.

Blinded veterans eligible for education and training under Public Law 16, receive in addition to tuition and fees a subsistence allowance from the Veterans Administration of $90 a month if they have dependents or $65 without dependents. Their disability compensation payments are not affected by these subsistence payments. If compensation and subsistence do not total at least $105 a month for a veteran with no dependents or $115 with one dependent, an additional sum is paid to make up the difference. The sum is further increased if there is more than one dependent.

HOSPITAL NEWSPAPERS

More than one hundred newspapers are published for patients in Veterans Administration hospitals and homes as a part of the program to aid in the medical rehabilitation of veterans. The papers are edited and staffed by patients and hospital employees, with the cooperation of officers who assign patients with certain disabilities to the newspaper staff as part of their treatment and vocational training. Patients with aptitudes for writing are encouraged to contribute to the papers for recreation. Most of these hospital newspapers are mimeographed; however, nine are printed on presses in the hospital's occupational therapy departments and four are multilithed.

Contests are being sponsored by the Advertising Club of Boston and the New York Advertising Club for the "best Veterans" Administration hospital newspaper in those sections of the country. When the contests close at the end of May plaques will be awarded to the winning paper in each area.

PLASTIC SURGERY CENTERS

The Veterans Administration has twenty-two plastic surgery centers for veterans in operation in Veterans Administration, army and navy hospitals over the country. These centers are manned by specialists skilled in plastic surgery and are provided with special equipment. They are in hospitals at West Roxbury, Mass.; Bronx, N. Y.; Washington, D. C.; Cleveland; Jefferson Barracks, Mo.; Fort Logan, Colorado; San Francisco; New Orleans; White River Junction, Vt.; Aspinwall, Pa.; Chamblee, Ga.; Hines, Ill.; McKinney, Texas; Los Angeles, and Van Nuys, Calif.

OPEN SUBREGIONAL OFFICE IN GARY, IND

Dr. Seymour R. Salberg has been appointed chief medical officer of the subregional office of the Veterans Administration in Gary, Ind. A graduate of the University of Illinois Medical School, Dr. Salberg formerly served also at a veterans' hospital in New York. The medical unit in this office when fully staffed will comprise twenty-seven persons, six of whom will be physicians, three dentists and several others technicians. There will also be x-ray and bacteriologic laboratories, hydrotherapy, physical therapy, a mental hygiene clinic and other services. The opening of this office will make it unnecessary for veterans in this vicinity to travel to the veterans' hospital at Hines, Ill., for examination and treatment.

VETERANS' HOSPITAL IN NEW YORK CITY

The 1,000 bed veterans' hospital to be constructed in New York City for general medical patients will be seventeen stories high with a penthouse and will cover a plot between 24th and 25th streets adjacent to the New York Medical School and Bellevue Hospital. The hospital will be of fireproof construction. The main structure will have, besides the hospital proper, a solarium on each floor and facilities for occupational therapy treatment, nurses' and staff quarters, chapel and auditorium. It will be constructed by the U. S. Army Corps of Engineers, the district office being in charge of Col. W. F. Heavey.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Course in Applications of Nuclear Physics.—A course in the applications of nuclear physics to the biologic and medical sciences will be given at the University of California Medical Center, San Francisco, June 30-July 18. The general subjects for the three weeks will be (1) an introduction to nuclear physics, (2) radioactive tracers in biology and medicine, (3) radioactive tracers, therapeutic and diagnostic applications of radio elements and health-physics. The instructors will be members of the various faculties of the University of California under the general direction of Dr. Stacy R. Mettier, associate professor of medicine, and under the general chairmanship of Dr. William J. Kerr, professor of medicine. The morning lecture periods will cover various phases of the subjects mentioned; in addition, special lectures and evening seminars will be given. The afternoons will be given over largely to laboratory work. Requests for registration should be addressed to Dr. Mettier, University of California Medical Center, San Francisco 22.

COLORADO

Studies of the Hypothalamic Region.—Two professors at the University of Colorado School of Medicine, Denver, received a grant totaling $24,000 from the Office of Navy Research. The grant was awarded to Robert M. Hill, Ph.D., professor of biochemistry, and Dr. Archibald R. Buchanan, professor of anatomy, for studies on the hypothalamic region of the brain in relation to the regulation of body temperature. Assisting Dr. Hill and Dr. Buchanan in their research are Dr. Enid K. Rutledge, associate professor of pathology, and Benjamin Robinson, James Roberts and Mrs. Alvey McChesney of the anatomy department.

Medical Research Club.—To stimulate correlation between basic sciences and clinical research, the faculty of the University of Colorado School of Medicine, Denver, and regional doctors have organized the Medical Research Club of Colorado. Membership is open to any one in the region interested in medical research or the allied sciences of physics, chemistry, biology and sociology. Monthly meetings will consist largely of reports on medical research in progress by club members. The club will meet in the clinical amphitheater of the University of Colorado School of Medicine, according to Dr. Abe Ravin, assistant professor of medicine and president of the club. The secretary is Dr. Dalton Jenkins, resident in medicine, University of Colorado School of Medicine, 4200 East Ninth Avenue, Denver.

Industrial Research.—To continue research in determining the effects of various heavy metals, particularly cadmium, on industrial workers, the National Institute of Health has renewed its grant for $28,512 to the division of industrial hygiene of the University of Colorado School of Medicine, Denver. The purpose of the research is to discover how much cadmium can be present in the air before it becomes harmful to workers in local smelters and also to determine how much cadmium can be present in body fluids before a toxic stage is reached and the workers must be removed from their jobs. Similar work has already been accomplished by the division of industrial hygiene in establishing safeguards for lead poisoning. The research is being carried on in the new research laboratory recently constructed in the division of industrial hygiene (THE JOURNAL, Dec. 21, 1946, p. 1019).

CONNECTICUT

State Medical Election.—At the annual meeting of the Connecticut State Medical Society April 29-30 Dr. James R. Miller, Hartford, assumed the office of president, succeeding Dr. Cole B. Gibson, Meriden, who was elected treasurer. Dr. Samuel C. Harvey, New Haven, was named president-elect, and Dr. Creighton Barker, New Haven, executive secretary. More than 1,000 physicians attended the meeting.

Appointment to Health Council.—Dr. W. Bradford Walker, Cornwall, was recently appointed by Governor James L. McConaughy as a member of the Connecticut Public Health Council for a term of six years, effective July 1. Formerly president of the Connecticut Public Health Association, Dr. Walker is a fellow of the American College of Physicians and attending senior physician at the Charlotte Hungerford Hospital, Torrington. He received his medical degree at the Yale University School of Medicine, New Haven, in 1920.

FLORIDA

Narcotic Violation.—Dr. Alfred E. O'Neil, 2554 South West Eighth Street, Miami, pleaded guilty to violation of the Federal Narcotic Law and on February 26 was sentenced to a term of eighteen months, which was suspended, and he was placed on probation for a period of three years.

Miami to Establish Medical School.—At a meeting April 16 the trustees of the University of Miami authorized the establishment of a school of medicine to be opened by October. The step was taken as the state legislature was debating bills to establish a medical and dental college as a branch of the University of Florida at Gainesville. Bowman F. Ashe, LL.D., president of the University of Miami, said that the decision of the trustees "has no connection" with the proposed state school. The city of Miami has offered 10 acres near the James M. Jackson Memorial Hospital as a site. The building is not needed to open the school, says Dr. Ashe, since first year's classes can be held in present classrooms.

ILLINOIS

Convicts Paroled Following Malarial Tests.—Seventy-six inmates of Statesville Prison, Joliet, who volunteered for wartime antimalarial experiments which yielded drugs helpful in the treatment and cure of malaria were paroled April 18. The prisoners had served an average of six years and fourteen days. A survey was conducted at the request of Governor Green by the correction division to determine what consideration should be given those who voluntarily submitted to the experiments. In a few cases in which factors unfavorable to parole predominated, the division entered "no change" orders.

Report on Disease Carriers.—A report from the Illinois Department of Public Health shows a reduction in the number of typhoid, paratyphoid and diphtheria cases and carriers in the last decade, as well as a comparison between the numbers in Chicago and downstate:

	State		Chicago		Downstate	
Year	Cases	Carriers	Cases	Carriers	Cases	Carriers
Typhoid and Paratyphoid						
1946	116	22	15	5	101	17
1937	540	54	75	10	465	44
Diphtheria						
1946	469	660	35	489	434	171
1937	1,671	1,918	655	1,802	1,016	116

From the ratio of cases to carriers reported in Illinois it can be seen, the report states, that Chicago has done a better job of discovering the year of carriers of virulent diphtheria organisms than the downstate communities.

Semicentennials.—Twelve eastern Illinois physicians who have had fifty or more years of practice received gold service buttons at the 8th District conference of the Illinois Medical Society in Mattoon April 17. They are Drs. Nicholas C. Iknayan, Charleston; Elijah G. Davis, Wakefield; Cyrus M. Harris, Casey; Dellie L. Wilhoit, Martinsville; Milton M. Brayshaw, Toledo; June J. Hinkley, Westfield; Alexis T. Telford and William E. Fritschle, Olney; John W. Kirk, Oblong; George E. Loesch, Palestine; Raymond C. Gillogly, Newman, and Edward H. Robinson, [illegible]akers were Dr. George A. Hellmuth [illegible] of Heart Disease"; Dr. James H. H[illegible], Chicago, "Common Endocrine Disturbances"; Dr. Charles E. Galloway, Evanston, "Early Diagnosis of Carcinoma of the Cervix"; Dr. Harry A. Oberhelman, Chicago, "Relationship of Chronic Cystic Mastitis to Cancer of the Breast"; Dr. G. Henry Mundt, Chicago, "Diagnosis and Management of Sinus Disease."

Chicago

Society of Internal Medicine.—The annual dinner of the Chicago Society of Internal Medicine will be held May 26 at the Drake Hotel at 7:30 for members only. Besides the annual business meeting Fay-Cooper Cole, Ph.D., professor and chairman of the department of anthropology, University of Chicago, will address the group on "Medicine Man."

The Mayo Lecture.—The Charles H. Mayo Lecture will be delivered May 21 at 4 p. m. in the Archibald Church Library of the Northwestern University Medical School by Dr. Herbert J. Seddons, Nuffield professor of orthopedic surgery, University of Oxford, and surgeon in chief, Winfield-Morris Orthopedic Hospital, London, on "Surgical Experiences in Peripheral Nerve Injuries."

Smoke Abatement Program.—During March Chicago's air was 27.5 per cent cleaner than in February, according to records obtained from twenty-two stations throughout the city. Newspaper publicity and an increase in rainfall in March over February is believed to account for the average of 57.99 tons of dust and smoke per square mile in March as compared to the citywide average of 80.38 tons in February.

Medical Editor Appointed.—Dr. Lee D. van Antwerp, Meriden, Conn., has been appointed to the newly created post of medical editor to G. D. Searle and Company, Chicago. Dr. van Antwerp, a graduate of the University of Michigan Medical School, Ann Arbor, in 1931, has served as editor of the *Centaur*, official publication of Alpha Kappa Kappa Medical Fraternity, since 1936. He served in the Army Medical Corps in the recent war and for many years has been connected with the Undercliff State Tuberculosis Sanatorium in Meriden, Conn., and as consultant in chest and medical diseases at the Meriden Hospital. He is a member of the American College of Physicians and of the American Medical Association.

Illinois Gets the Hertzler Manuscripts.—The University of Illinois College of Medicine has received manuscripts for four books, thirty-four unpublished addresses and miscellaneous writings by the late Dr. Arthur E. Hertzler, famed "horse and buggy doctor" of Halstead, Kan., from his widow, Dr. Irene A. Koeneke. The original manuscript of "The Horse and Buggy Doctor," first published in 1938, will be presented to the university by Dr. Koeneke in the near future. Publication of the addresses under the title "The Doctor Speaks His Mind" was halted by Dr. Hertzler's death on Sept. 12, 1946, at the age of 76. The manuscripts will be added to the 7,000 volume private medical library which Dr. Hertzler presented to the university in 1937. In addition to the gifts, Dr. Hertzler contributed $54,000 to the university three years ago to establish a foundation in visual education and medicine.

LOUISIANA

Decrease in Typhus Cases.—Since the resumption of an extensive rat control program in Louisiana during 1944 a substantial reduction in typhus cases in the state has been noted. The program consisted in rat poisoning, DDT dusting and rat proofing. During 1946 an intensified control program practically covered the state. The expenditure for 1946 was about $420,000. Typhus cases decreased from 423 in 1945 to 288 in 1946, a 32 per cent decline. The decline of cases in the state, exclusive of New Orleans, where the campaign is still not widespread, was from 306 in 1945 to 168 in 1946, a drop of 45 per cent.

MICHIGAN

Changes in Health Officers.—Dr. William C. Harrison, formerly of Minneapolis, will assume duties as director of the Delta-Menominee district health department at Powers, Mich., July 1. The two county health unit will be merged when he takes charge. Dr. Harrison, a graduate of the University of Minnesota Medical School, Minneapolis, practiced medicine in Minnesota until he entered military service and was discharged with the rank of lieutenant colonel. He is attending the school of public health, where he will receive his master's degree.——Dr. Russell E. Pleune has resigned as director, Northern Peninsula office, state department of health, and has accepted the position of chief, tuberculosis section, McCloskey Veterans' Hospital, Temple, Texas. Dr. Pleune is a graduate of Rush Medical School, University of Chicago, and completed his studies in public health work at Harvard Medical School, Boston.

Annual Alumni Clinic Day.—Wayne University College of Medicine (Detroit) alumni held their Annual Clinic Day May 14. Guest speakers included Drs. Emery A. Rovenstine, professor of anesthesia, New York University College of Medicine, New York, "Nerve Block Therapy"; W. Wayne Babcock, professor of surgery and clinical surgery, surgeon in chief, Samaritan Hospital, Philadelphia, "Complications of Abdominal Surgery"; John H. Couch, University of Toronto, Toronto, "Conservation of Function in Hand Amputations"; Kenneth F. Lowry, Ohio State University College of Medicine, Columbus, Ohio, "Application of Delayed Suture in the Management of Wounds"; Tom D. Spies, director of Nutrition Clinic, Hillman Hospital, Birmingham, Ala., "Recent Advances in Nutrition"; Louis H. Newburgh, professor of clinical investigation, University of Michigan Medical School, Ann Arbor, "Work of the Kidney Cells." Life membership in the association and "golden anniversary" certificates were awarded the sixteen surviving members of the graduating class of 1897 at the banquet.

MINNESOTA

Society News.—At a recent meeting of the Minneapolis Surgical Society, Dr. L. Haynes Fowler was elected president, succeeding Dr. Thomas J. Kinsella; Drs. Carl O. Rice vice president, Rudolph E. Hultkrans treasurer and Ernest R. Anderson secretary.

Regional Cancer Courses.—One day regional continuation courses for medical and lay workers in cancer education began in Worthington March 25, with similar regional monthly meetings scheduled for all sections of the state for the rest of the year except July and August. They are under a joint sponsorship of the Minnesota Department of Health, Minnesota Cancer Society, the University of Minnesota and the state medical association. Talks and demonstrations by cancer specialists from the university and by local physicians will provide the information about cancer. At the annual meeting of the Minnesota Cancer Society in March the society voted to change its official name to Minnesota Division, American Cancer Society, Inc. At the same time it presented the University of Minnesota with $75,000 toward a cancer research institute and, with the state department of health, set aside $15,000 for a cancer detection center.

MISSOURI

Personal.—Dr. Evarts A. Graham, professor of surgery, Washington University School of Medicine, St. Louis, has been made an honorary member of the Belgian Society of Surgery and of the French Academy of Surgery.

Society Elections.—Dr. W. Barry Wood, professor of medicine, Washington University School of Medicine, St. Louis, was elected president of the St. Louis Society of Medicine at a recent meeting.——Dr. Wendell G. Scott, associate professor of clinical radiology, Washington University School of Medicine, St. Louis, was reelected president of the St. Louis Radiological Society for the coming year.

St. Joseph Clinical Society.—At a meeting of this society in St. Joseph, April 23-24, the subjects discussed included diagnosis and treatment of pulmonary embolism, duodenal ulcer in children and cirrhosis of the liver. Among the guest speakers were Dr. Louis A. Brinsting, associate professor of dermatology and syphilology, Mayo Clinic, Rochester, Minn., "Recent Developments in the Treatment of Syphilis"; Dr. John M. Waugh, assistant professor of surgery, Mayo Clinic, "Carcinoma of the Rectosigmoidal Area," and Dr. Harold C. Lueth, dean and professor of medicine, University of Nebraska College of Medicine, Omaha, "Management of Coronary Thrombosis in the Younger Patient."

NEW YORK

Home for the Aged.—Mr. Isidore Greenspan, executive director of the Brooklyn Hebrew Home and Hospital for the Aged, celebrated his twenty-five year association with that institution on May 1. From a home of 109 beds the institution has grown to be a home and hospital for chronic seniors, with a capacity of 711. Plans are under way for a new 400 bed structure and modernization plans of the older properties.

Annual Reifenstein Lecture.—The annual Edward C. Reifenstein Lecture in medicine was given April 22 at the Syracuse University College of Medicine auditorium, Syracuse, by Dr. George W. Thorn, Hersey professor of the theory and practice of physic, Harvard Medical School, and physician in chief, Peter Bent Brigham Hospital, Boston, on "Diagnosis and Treatment of Adrenal Cortical Insufficiency."

Cancer Control in Wayne County.—A plan for the early detection and treatment of cancer has been charted by the recently organized Wayne County Branch, New York State Division, American Cancer Society, in collaboration with the county medical society. The plan includes a complete physical examination for every person in the county, medical records of patients in the Wayne County Laboratory and a speakers' bureau established by the medical society to assist in the educational program. Every town and local organization will conduct an educational cancer program during the year.

New York City

Eighth Harvey Lecture.—Dr. Samuel Z. Levine, New York, professor of pediatrics, Cornell University Medical College, New York, delivered the eighth Harvey Lecture of the current series at the New York Academy of Medicine May 15 on "Aromatic Amino Acid Metabolism in Human Nutrition and the Role of Vitamin C."

Postgraduate Course in Rheumatic Fever.—A postgraduate course in rheumatic fever and rheumatic heart disease will be conducted at St. Francis Sanatorium for Cardiac Children, Roslyn, L. I., July 14-25. Informal lectures and discussions supplemented by examination and study of patients, roentgenography and electrocardiography and their practical application will be given. For further information address Rev. Mother Superior, F.M.M., St. Francis Sanatorium for Cardiac Children, Roslyn, Long Island, N. Y.

Society Honors Seven and Forty-Nine Members.—The Richmond County Medical Society feted seven physicians who have been members for forty years on April 9 at the fifty-third annual dinner of the society in Staten Island. The physicians are Drs. Charles L. Allers, Frederick Coonley, Charles E. Pearson, H. MacDonald Peggs, Robert N. Severance, Richard M. MacRae and Myron B. Morris. A plaque engraved with the names of forty-nine members who served in the armed forces was presented to Dr. Stanley C. Pettit, who represented the veterans.

The Health Examination.—The Community Service Society, 105 East Twenty-Second Street, has just published a pamphlet entitled The Health Examination, for public health nurses to use as a guide in family health service and to help them prepare individuals and families for going to doctors for health examinations. The pamphlet contains illustrations of various phases of the health examination and quotations from authorities who have expressed opinions on health examinations; also a copy of the form which the physician may fill out when the examination is given. The pamphlet, which has been revised up to January 1 of this year, sells at 25 cents each for orders under 100 copies and 20 cents for orders above that number.

NORTH CAROLINA

Dr. Edward McGavran Appointed Dean.—Dr. Edward G. McGavran, professor of public health and preventive medicine, University of Kansas School of Medicine, Lawrence-Kansas City, Kan., has been appointed dean of the School of Public Health, University of North Carolina, Chapel Hill, effective September 1. Dr. McGavran received his medical degree from Harvard Medical School, 1928, and his M.P.H. from the Harvard School of Public Health. From 1934 to 1939 he was director of health and county health officer in Hillsdale, Mich., for the W. K. Kellogg Foundation, which he served the following year on a survey of health conditions in the sugar industry in Hawaii. He served as health commissioner of St. Louis County, Mo., 1941-1946.

PENNSYLVANIA

Diarrhea Epidemic in Infants.—Twenty-two babies in Pennsylvania have died since March 1 of gastroenteritis, 18 of them in Allentown, 4 in Philadelphia and 6 others in Somerville, N. J. At Temple University Hospital, Philadelphia, 32 children brought from Allentown and being cared for in an isolated ward were reported in "good condition." At Somerville 10 others are still ill in an isolated ward of Somerset Hospital but are not regarded as in a serious condition.

Philadelphia

Residents Banquet at Atlantic City.—The Association of Resident and Ex-Resident Physicians of the Philadelphia General Hospital will hold its first annual alumni reunion banquet at the Centennial Celebration of the A. M. A. in Atlantic City June 11 at 7 o'clock at Haddon Hall. Invitations have been issued to all members of the association; any who fail to receive them may make reservations through Dr. Robert C. McElroy, secretary-treasurer, 133 South 36th Street, Philadelphia 4.

Pittsburgh

Pittsburgh Surgical Society.—The Pittsburgh Surgical Society held a meeting at Mellon Institute Friday, May 16, to which all members of the Allegheny County and surrounding medical societies were invited. Dr. Edward M. Kent, St. Louis, spoke on "Bronchogenic Carcinoma," and Dr. Samuel P. Harbison, Sewickley, Pa., discussed "Reparative Surgery of Soft Part Wounds."

RHODE ISLAND

New County Society.—The house of delegates of the state medical association has issued a charter to the physicians of Bristol County to permit them to form a constituent association in that area. The action removes the Bristol delegation from the jurisdiction of the Providence Medical Association. Dr. Marcius H. Merchant is the first president of the new association.

TEXAS

Grant for Experimental Study.—A special grant of $10,000 has been approved by the U. S. Public Health Service for the support of a study of experimental vascular syphilis under the direction of Dr. Chester N. Frazier in the laboratories of the department of dermatology and syphilology of the University of Texas Medical Branch, Galveston.

University News.—Ardzroony Packchanian, Ph.D., associate professor of bacteriology and parasitology at the University of Texas Medical Branch, Galveston, left for Mexico April 21. He was a visiting professor of bacteriology and tropical medicine at the Escuela de Midicina de Nuevo León in Monterrey and lectured on leishmaniasis, trypanosomiasis, spirochetosis and tularemia. The Mexican government has also invited him to do field research. He was expected to return to Galveston about May 10.

Texas Medical Center.—A campaign is in progress to raise money needed to construct the $2,500,000 St. Luke's Hospital, which is to be built by the Episcopal Church as a part of the Texas Medical Center at Houston. Mr. and Mrs. R. H. Cullen, Houston, have given $1,000,000, and $500,000 has been received from the M. D. Anderson Foundation of Houston. A 6 acre site is a further gift from the Anderson Foundation. The hospital will have 250 beds. The Texas Medical Center is expected to include the Baylor Medical School, University of Texas Dental School, Hermann Hospital, a children's hospital, tuberculosis hospital, nurses' training school, x-ray laboratory and pathologic laboratory, and specialized study for pediatrics, geriatrics and numerous other phases of medicine.

WISCONSIN

Honored for Service to Community.—Drs. Jean A. Jackson and Edward F. Butler, Mosinee, were honored at a testimonial dinner in March sponsored by the Mosinee Chamber of Commerce and the Lions Club in recognition of the doctors' long and faithful service to their community. Dr. Butler has spent his entire medical career, thirty-six years, in Mosinee, and Dr. Jackson moved to the city thirty years ago.

GENERAL

State Postgraduate Committees Meeting.—The next meeting of the Associated States Postgraduate Committees will be held June 11, 12:30 p. m., at Chalfonte-Haddon Hall, Atlantic City. The subject will be the scope of postgraduate programs offered by a state medical society.

Diploma Stolen.—Dr. Frederick S. Spearman of Williams, Ariz., a graduate of McGill University Faculty of Medicine, Montreal, Canada, reports that his medical diploma has been stolen and suggests that state medical boards be on the watch in case some one should attempt to register by means of it.

Loyola Alumni Meeting in Atlantic City.—The Medical Chapter of the Loyola University Alumni Association will hold a dinner for 200 alumni and their wives at the Chelsea Hotel in Atlantic City June 11 at 6:30. The main speaker will be Dr. James J. Smith, dean of Loyola University School of Medicine, Chicago. The New Jersey club president is Dr. I. Jerome Sobel of Passaic, N. J.

Metropolitan Says Our Health Is Best Ever.—Health in the United States was better in the first quarter of 1947 than ever before in the same period, according to Metropolitan Life Insurance Company records. Mortality for the first three months was 7.7 deaths for each thousand policyholders, or 9.8 per cent below the rate for the like months of 1946 and 3.6 per cent below the previous low for the period registered in 1945. New lows in death rates were registered for tuberculosis, the four principal communicable diseases of childhood as a group, syphilis and appendicitis.

Special Society Elections.—The Southern Society of Clinical Surgeons at a recent meeting elected Dr. Emmett B. Frazer, Mobile, Ala., president, and Dr. James White, Fort Worth, Texas, vice president.——The National Academy of Sciences at its annual meeting in Washington April 28-30 elected the following officers: president for a four year term, Alfred N. Richards, Sc.D., Ph.D., vice president in charge of medical affairs, University of Pennsylvania, Philadelphia, and secretary for a further four year term, Frederick E. Wright, Sc.D., Carnegie Institution, Washington, D. C.

American Urological Association Meeting.—The twenty-third annual meeting of the western section of the American Urological Association will be May 21-23 at the Ahwahnee Hotel, Yosemite Valley, Calif. Among the subjects of many scientific papers to be presented are streptomycin and the urologist, surgical treatment of hypertension, urologic manifestations in early filariasis and the best method of removal for adenoma of the prostate. The president's address will be delivered May 22 at 1:30 by Dr. Dudley P. Fagerstrom, San Jose, Calif., on "Proliferative Tumors of the Ureter and Renal Pelvis, with Further Observations on the Significance of Epithelial Nests."

Institutes in Hospital Administration.—The American Hospital Association, 18 East Division Street, Chicago, will sponsor during the next six months a series of institutes of several days' duration on specialized phases of hospital administration. They will consist of talks, panel discussions and informal discussion of individual hospital contracts. The first institute, at the Continental Hotel, Chicago, May 19-23, on Hospital Pharmacy, will be co-sponsored by the American Pharmaceutical Association. The last of the series will be an institute for hospital trustees held in Chicago, December 1-5. Between these dates institutes will be held at various other cities on such subjects as public relations, personnel management, cost analysis and anesthetics.

Tuberculosis Physicians to Meet in Atlantic City.—The annual meeting of the American Academy of Tuberculosis Physicians will be held at the Hotel Dennis, Atlantic City, N. J., June 7. Under the leadership of Dr. Marcio M. Bueno, Rio de Janeiro, Brazil, a delegation from South America will attend. Included in the subjects of papers to be presented are Bagasse disease, case finding in the schools of Detroit, postoperative care following thoracic surgery, air embolism during pneumoperitoneum and safeguarding the undergraduate and graduate student of medicine against tuberculosis. Guest speakers will be Dr. Bueno, whose address will be "The Prevention of Tuberculosis," and Dr. Konrad Birkhaug, state department of health, Albany, N. Y., whose subject will be "Experimental and Clinical Basis for BCG Vaccination."

New Organization for Pathologists.—The College of American Pathologists, formed Dec. 13, 1946, has opened a temporary office at 203 North Wabash Avenue, Chicago. The objectives of the organization are (*a*) to foster the highest standards in education, research and the practice of pathology; (*b*) through study, education and improvement of the economic aspects of pathology to advance the science of pathology and to improve medical laboratory service; (*c*) to maintain the dignity, precision and efficiency of the specialty of pathology for the service of the common good. Membership is limited to pathologists certified by the American Board of Pathology. Junior membership is available to residents in pathology who have completed two years of their requirements for examination by the American Board of Pathology. Officers of the organization are Drs. Frank W. Hartman, Henry Ford Hospital, Detroit, president; Tracy B. Mallory, Massachusetts General Hospital, Boston, secretary-treasurer, and Melbourne G. Westmoreland, Chicago, executive secretary.

Gastroscopic Club to Meet at Atlantic City.—The third annual meeting of the American Gastroscopic Club is to be held at the Hotel Claridge, Atlantic City, June 8 at 9:30 a. m. Among the speakers will be Dr. Rudolf Schindler, Los Angeles, on "Differentiation of Benign and Malignant Gastric Ulcer"; Drs. Moses Paulson, Baltimore, and Eugene S. Gladsden, Washington, D. C., "Partial Gastrectomy: Clinical, Gastroscopic and Radiological Considerations"; Dr. Regis A. Wolff, Pittsburgh, "Gastroscopic Appearance of the Gastric Mucosa Before and After Vagus Resection"; Dr. Frank McGlone, Denver, "Observations on Gastritis Based on Experience in a General Hospital in the South Pacific"; Dr. I. Richard Schwartz, Brooklyn, "Gastroscopic Observations in Secondary Syphilis"; Dr. Cecil O. Patterson, Dallas, Texas, "Description of the Gastroscopic Appearance of Luetic Lesions in the Stomach," and Drs. Harry L. Segal and James S. Watson Jr., Rochester, N. Y., "Color Photography Through the Flexible Gastroscope." A business meeting and a luncheon will follow the scientific program with Dr. Henry L. Bockus, Philadelphia, the speaker.

Dr. Ross G. Harrison Receives Carti Medal.—Dr. Ross G. Harrison, professor emeritus, Osborn Zoological Laboratory, Yale University, New Haven, Conn., received the John J. Carti gold medal and award for 1947 at the annual dinner of the National Academy of Sciences, Washington, D. C., April 29. The award was conferred for the discovery that tissue cells may be grown outside the animal body and by the use of the discovery to demonstrate the manner of growth of nerve fibers, for long and distinguished service as investigator, teacher and councilor of students and for a statesmanly direction of the National Research Council. As a young man at Johns Hopkins University, Baltimore, he obtained striking experimental results in a study of the development of the nervous system. He first used the method of isolation of embryonic tissues in culture mediums and gave an ocular demonstration that the nerve fiber grows out from a single cell without the participation of accessory cells. This led to the procedure known as tissue culture, which has since been widely used in the differentiation, growth and behavior of cells under various conditions outside the body. Referring to Dr. Harrison's work on the nerve fiber, Dr. Florence R. Sabin, Denver, retired, has said "This epochal discovery, with all of the developments of the methods of studying living cells, is one of the most outstanding American contributions to scientific medicine and biology." Provision for the Carti Medal and Award was made by the American Telephone and Telegraph Company as a token of esteem on the occasion of the late John J. Carti's retirement from active service.

FOREIGN

Malaria Among the Moros.—The Associated Press reports that a malaria epidemic in Mindanao, Philippine Islands, is taking the lives of 800 to 1,000 Moros a month. Governor Louis R. Marohonbsar of Lanao province has appealed to the UNRRA and the Philippine government to help combat the spread of malaria among the 300,000 Moros inhabiting fertile uplands bordering the Lake Lanao region.

Reorganization of Japanese Medical Association.—The first issue of the *Journal of the Japanese Medical Association* to be published after its reorganization under democratic principles has come to this office and is printed in the Japanese language. The Japanese Medical Association previously had been a government agency for the control of the medical profession under which membership was compulsory by law and the government appointed the national and state (prefectural) presidents. The association has been reorganized under the guidance of the public health and welfare section, General Headquarters, Supreme Commander for the Allied Powers. It is now an association representing the medical association with voluntary membership which selects its own officers. Col. Crawford F. Sams, M. C., U. S. Army, chief of the public health and welfare section, writes that this process of turning an organization completely upside down has been a long and tedious one.

Palestine Society for Medical History.—The first conference of the Palestine Society for Medical History was held in Jerusalem April 7. On the following day lectures were continued at the Hebrew University. Among others, a paper presented by the late Dr. M. Meyerhof, Cairo, Egypt, entitled "Arabic Medicine Among Yemenite Jews," was read by Dr. D. A. Friedmann, editor, *Journal of the Palestine Medical Association*. The honorary president of this organization is Dr. Harry Friedenwald, Baltimore. The address of the organization is Street of Prophets, Baltinester House, Jerusalem. The object of the Palestine Society for Medical History is research into and propagation of knowledge in medical history and all its branches, particularly research in Jewish medical history. The society will have its own quarterly publication and a library with old manuscripts, especially photostats of manuscripts. It will support research workers and distribute a prize for the most important paper of the past year.

CORRECTIONS

Price of Book.—Under Book Notices in The Journal, April 26, page 1319, the price of the book "Pharmacy's Part in Society," by George Urdang, was given as $1.05. The price of the book is $5.

The Repair of Arteriovenous Fistulas.—In the paper by Heringman, Rives and Davis (The Journal, March 8, p. 663) the footnote under the title should read "From the Department of Surgery, Louisiana State University School of Medicine, and the Surgical Services of Charity Hospital of Louisiana and Touro Infirmary." On page 667 the last sentence of the legend for figure 8 should begin "Although this is not an arteriovenous aneurysm . . ."

Marriages

Mark Stiles Wellington, St. Petersburg, Fla., to Miss Patricia Anne Sampson of Plymouth, Mass., Dec. 10, 1946.

Charles E. Thompson, Omaha, to Miss Martha Jane Wheat of Belleville, Ill., Dec. 10, 1946.

Sidney Martin Samis to Miss Shirley Gladys Aronow, both of New York, March 16.

Samuel Sherman to Miss Constance Sara Sameth, both of New York, February 16.

Deaths

Isidore William Held ⊕ New York; born in Boryslav, Austria, May 15, 1876; Jefferson Medical College of Philadelphia, 1902; from 1935 to 1941 clinical professor of medicine at the New York University College of Medicine, where the I. W. Held Fellowship Fund had been established in his honor; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the National Gastroenterological Association, American Heart Association, American Association for the Advancement of Science, Association of Military Surgeons of the United States and others; consulting physician and from 1929 to 1945 attending physician at the Beth Israel Hospital, where the pathologic laboratory is named in his honor; consulting physician at the Nathan and Miriam Barnet Memorial Hospital, Paterson, N. J., Israel Zion, Beth Moses and Beth El hospitals in Brooklyn, Jewish Memorial Hospital and the Rockaway Beach (N. Y.) Hospital; major, medical reserve corps, not on active duty; co-author of "Peptic Ulcer—Its Diagnosis and Treatment"; died in the Mount Sinai Hospital March 2, aged 70, of cardiovascular disease and acute pyelonephritis.

Cornelius Albertus Hospers ⊕ Chicago; School of Medicine of the Division of the Biological Sciences, University of Chicago, 1932; interned at University of Chicago Clinics; specialist certified by the American Board of Pathology, Inc.; member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists; on the staffs of the Holy Cross and South Chicago Community hospitals; served as a lieutenant colonel in the medical corps, Army of the United States, during World War II; died February 20, aged 42, of coronary thrombosis.

Robert Brian Archibald ⊕ Bedford Hills, N. Y.; Dalhousie University Faculty of Medicine, Halifax, N. S., Canada, 1927; president, past vice president and secretary of the Westchester County Medical Society; at one time health officer of Covington County, Ala.; affiliated with the Northern Westchester Hospital in Mount Kisco; on the editorial board of the *Westchester Medical Bulletin*; died February 7, aged 46.

Herman Charney ⊕ Greeley, Colo.; St. Louis College of Physicians and Surgeons, 1926; died in the Montefiore Hospital in New York February 5, aged 45, of recurrent brain tumor.

Otto H. Duker, Baltimore; College of Physicians and Surgeons, Baltimore, 1904; died in St. Joseph's Hospital January 19, aged 79, of arteriosclerosis and thrombosis of femoral artery.

Harry Charles Durkee, Woodstock, Ill.; State University of Iowa College of Medicine, Iowa City, 1906; member of the American Medical Association; died February 16, aged 67, of cerebral hemorrhage.

George Spaulding Edwards, Santa Barbara, Calif.; University of Southern California School of Medicine, Los Angeles, 1943; interned at the Los Angeles County Hospital in Los Angeles; instructor in physiology at his alma mater; served during World War II; died in January, aged 29, of hemorrhagic consolidation of lungs due to pharyngeal hemorrhage during syncope of unknown etiology.

C. Bryant Elkins, Springfield, Mo.; Missouri Medical College, St. Louis, 1885; member of the American Medical Association; honorary member of the Missouri State Medical Association; died in St. John's Hospital February 25, aged 85, of coronary thrombosis.

Daniel James Ellison ⊕ Lowell, Mass.; Tufts College Medical School, Boston, 1908; member of the New England Obstetrical and Gynecological Society; served during World War I; past president of the Middlesex North District Medical Society; affiliated with the Lowell General, St. John's and St. Joseph's Hospitals; died February 14, aged 62, of cerebral hemorrhage.

Charles William Eustace ⊕ Buffalo; University of Buffalo School of Medicine, 1910; for many years chief examiner in the area for the Travelers Insurance Company of Hartford; awarded certificate of merit for service given Selective Service System; died February 9, aged 69, of coronary thrombosis.

Lee Thaddeus Ferrell, Albuquerque, N. M.; University of Nashville (Tenn.) Medical Department, 1911; served during World War I; for many years on the staff of the Veterans Administration Center, where he died February 3, aged 67, of coronary occlusion.

George Earl Fortmiller, Albany, Ore.; University of Oregon Medical School, Portland, 1918; formerly city and county health officer; on the staff of the Albany General Hospital, where he died February 19, aged 55, of heart disease.

Sanford Edwin Gaines ⊕ Sparta, Tenn.; University of Tennessee College of Medicine, Memphis, 1890; an Affiliate Fellow of the American Medical Association; for many years county health officer; past president of the Upper Cumberland Medical Society; on the staff of the White County Hospital; died February 19, aged 78, of myocarditis.

Edward Francis Garraghan ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; at one time on the faculty of Rush Medical College; on the staffs of the Columbus Memorial Hospital and St. Joseph's Hospital, where he died March 10, aged 73, of carcinoma of the pancreas.

John Aldridge Gibson ⊕ Leesburg, Va.; University of Maryland School of Medicine, Baltimore, 1901; served as vice president of the Medical Society of Virginia and as president of the Loudoun County Medical Society; affiliated with the Loudoun County Hospital, where he died March 10, aged 70, of carcinoma of the gallbladder.

Guy Aubrey Gowen, Chicago; Northwestern University Medical School, Chicago, 1896; member of the American Medical Association; died March 9, aged 77, of hypertension and cerebral hemorrhage.

John Denton Green, Brookville, Miss.; Loyola University School of Medicine, Chicago, 1918; member of the American Medical Association; served as president of the North East Mississippi Thirteen County Medical Association and as health officer of Noxubee County; died in the Methodist Hospital, Memphis, Tenn., February 4, aged 67, of carcinoma of the cecum.

Laborn James Harley, Atlanta, Ga.; University of Nashville (Tenn.) Medical Department, 1900; served during World War I; died in Veterans Hospital number 48, February 16, aged 72, of cerebral thrombosis and hypertensive heart disease.

Frank Crawford Hayes, Camden, Ill.; George Washington University School of Medicine, Washington, D. C., 1905; at one time connected with the Indian Service; died in the Blessing Hospital, Quincy, February 24, aged 76, following the removal of an infected kidney.

Hamilton Worth Hewit, Lincoln, Neb.; Rush Medical College, Chicago, 1877; died in the Lincoln General Hospital February 18, aged 96, of arteriosclerosis.

John Joseph Hill, Forest Hills, N. Y.; Fordham University School of Medicine, New York, 1912; medical officer of the New York Fire Department; served on the staffs of the Beekman Street, Bellevue and St. Joseph's hospitals, all in New York; died in the Bronx Hospital, New York, February 21, aged 62, of coronary thrombosis.

Richard Gordon Holcombe, Lake Charles, La.; Tulane University of Louisiana, New Orleans, 1906; member of the American Medical Association; on the staff of St. Patrick's Hospital; died February 5, aged 65, of cerebral hemorrhage.

Richard M. Howe, St. Petersburg, Fla.; Eclectic Medical Institute, Cincinnati, 1889; died in St. Anthony's Hospital March 3, aged 81, of myelogenous leukemia.

Jesse William Ingram, Walla Walla, Wash.; University of Nashville (Tenn.) Medical Department, 1902; member of the American Medical Association; past president of the Walla Walla Valley Medical Society; served as treasurer of the state board of medical examiners; for many years physician for the state penitentiary; served overseas during World War I; lieutenant colonel, medical reserve corps, not on active duty; formerly county health officer; died in the Veterans Hospital, American Lake, February 22, aged 71, of organic heart disease.

Gabriel Joseph Jack ⊕ North Haven, Conn.; Boston University School of Medicine, 1907; fellow of the American College of Surgeons; on the staff of the Grace Hospital in New Haven; died February 6, aged 63, of coronary occlusion.

John Greenwood Jennings ⊕ Boston; Tufts College Medical School, Boston, 1915; member of the New England Ophthalmological Society; flight surgeon during World War I; served on the staffs of the Massachusetts Eye and Ear Infirmary in Boston and the Waltham (Mass.) Hospital, where he died February 17, aged 58, of internal hemorrhages.

Griffith Smith Jones, Genesee Depot, Wis.; University of Pennsylvania School of Medicine, Philadelphia, 1917; member of the American Medical Association; at one time school health officer in Wauwatosa; died in the Wisconsin General Hospital in Madison February 7, aged 63, of postoperative pneumonitis.

Lewis J. Jones, Stanford, Ky.; Hospital College of Medicine, Louisville, 1902; member of the American Medical Association; secretary-treasurer of the Lincoln County Medical Society; veteran of the Spanish-American War; died February 13, aged 66, of heart disease.

Shelby Justus, Swifton, Ark. (licensed in Arkansas in 1909); member of the American Medical Association; died in Searcy February 16, aged 66, of coronary thrombosis and duodenal ulcer.

Roscoe Romeo Kahle ⊕ Columbus, Ohio; Starling Medical College, Columbus, 1904; on the staffs of the Grant and St. Anthony's hospitals; died February 7, aged 68, of coronary thrombosis.

Ira Nelson Kilburn, Springfield, Mass.; Dartmouth Medical School, Hanover, N. H., 1911; member of the American Medical Association; member of the Springfield Academy of Medicine; on the staffs of the Wesson Memorial and Springfield hospitals; died February 2, aged 61, of cerebral hemorrhage and arteriosclerosis.

Ray Porter Kile, Rockford, Ill.; University of Illinois College of Medicine, Chicago, 1913; member of the American Medical Association and the American Urological Association; died in Tucson, Ariz., February 19, aged 62, of intestinal obstruction.

Harvey Thomas Little ⊕ Chicago; Loyola University School of Medicine, Chicago, 1916; member of the staffs of the Loretto and County hospitals; died in Hollywood, Calif.; March 10, aged 52, of coronary thrombosis.

Myrtle Ethel Spencer Lockwood, National City, Calif.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1900; member of the American Medical Association; on the staff of the Paradise Valley Sanitarium and Hospital, where she died February 5, aged 70, of carcinoma of the tongue.

Albert H. Macbeth, Fort Wayne, Ind.; University of Buffalo School of Medicine, 1892; member of the American Medical Association; veteran of the Spanish-American War; served as a staff member of St. Joseph's, Lutheran and Methodist hospitals; formerly health commissioner; died March 10, aged 83.

Oscar Hunter McClung, Lexington, Va.; University of Virginia Department of Medicine, Charlottesville, 1902; member of the American Medical Association; on the staff of the Jackson Memorial Hospital; died February 2, aged 67, of coronary thrombosis.

Alva Edgar McReynolds, El Paso, Ill.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1915; member of the American Medical Association; served overseas during World War I; during World War II received the Congressional Medal of Merit for work in civilian defense; died February 6, aged 70, of coronary occlusion.

U. Rial McReynolds, Knox City, Mo.; St. Louis University School of Medicine, 1904; member of the American Medical Association; died February 12, aged 66, of aortic stenosis.

John A. May, Manchester, Iowa; Chicago Homeopathic Medical College, 1890; died recently, aged 83, of coronary sclerosis.

Paul Mazzuri, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1897; veteran of the Spanish-American War; an associate of Walter Reed during the famous yellow fever experiments in Cuba in 1900; formerly assistant medical director of the New York Life Insurance Company; died in the Touro Infirmary March 9, aged 81, of arteriosclerosis and bronchopneumonia.

Benjamin Franklin Myers, Chambersburg, Pa.; Baltimore Medical College, 1892; member of the American Medical Association; past president of the Franklin County Medical Society; served as county jail physician; on the staff of the Chambersburg Hospital, where he died February 17, aged 78, of carcinoma of the stomach.

Mary Eva Gill Noble, Brookline, Mass.; Tufts College Medical School, Boston, 1902; member of the American Medical Association; specialist certified by the American Board of Psychiatry and Neurology; for many years on the staff of the Boston State Hospital; died in the New England Hospital, Boston, February 16, aged 75, of cerebral hemorrhage.

John T. O'Mara ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1903; secretary of the board of medical examiners of Maryland for twenty-two years; member of the Federation of State Medical Boards of the United States; fellow of the American College of Physicians; on the staff of the Bon Secours and St. Agnes hospitals; died February 3, aged 66, of cerebral hemorrhage.

Thomas Edward Phillips, Alligator, Miss.; Tulane University of Louisiana, New Orleans, 1910; member of the American Medical Association; served during World War I; died in the Clarksdale (Miss.) Hospital February 14, aged 59, of heart disease.

Joseph B. Potsdamer, Philadelphia; Jefferson Medical College of Philadelphia, 1879; member of the American Medical Association; served on the staff of the Jewish Hospital; died February 14, aged 89, of pneumonia.

Addison Webster Preston ⊕ Visalia, Calif.; University of Vermont College of Medicine, Burlington, 1907; for many years city and county health officer; director of the Bank of America; served as a member of the school board; died February 5, aged 63, of pyelonephritis.

Joseph Larcher Ravitts, Montezuma, Iowa; Chicago College of Medicine and Surgery, 1914; member of the American Medical Association; served during World War I; examining physician for the Poweshiek County Selective Service Board during World War II; died February 5, aged 62, of cerebral hemorrhage.

Maurice Joseph Reidy ⊕ Winsted, Conn.; Columbia University College of Physicians and Surgeons, New York, 1910; fellow of the American College of Surgeons; affiliated with the Litchfield County Hospital; died in St. Francis Hospital, Hartford, February 6, aged 62, of cerebral thrombosis.

Knight Reynolds ⊕ Cumberland, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1925; on the staff of the Memorial Hospital; died February 5, aged 47.

Abbott Satterthwait, Laguna Beach, Calif.; Hahnemann Medical College and Hospital, Philadelphia, 1897; died February 11, aged 73.

Charles Hamilton Schultz ⊕ Johnstown, Pa.; George Washington University School of Medicine, Washington, D. C., 1922; served during World War I; during World War II served as a medical examiner for a local selective service board; for many years affiliated with the Memorial and Mercy hospitals; died February 6, aged 52.

Frank Robert Sedgley, Redwood City, Calif.; Boston University School of Medicine, 1902; member of the American Medical Association and the Massachusetts Medical Society; fellow of the American College of Surgeons; formerly affiliated with the U. S. Public Health Service Reserve and on the staffs of various Veterans Administration hospitals; died February 13, aged 67, of coronary occlusion.

Monroe Shaul, Boonville, Ind.; Kentucky School of Medicine, Louisville, 1883; died February 15, aged 93, of senility.

William Mark Sherman, St. Louis; St. Louis University School of Medicine, 1904; for many years medical examiner for the John Hancock Mutual Life Insurance Company; died in the City Hospital February 7, aged 76, of arteriosclerosis and cerebral thrombosis.

George W. Sholler ⊕ Melrose Park, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; past president of the Philadelphia County Medical Society; affiliated with the Jewish Hospital and Germantown Hospital in Philadelphia, where he died February 3, aged 76, of coronary occlusion.

William Walter Slayden, Waverly, Tenn.; University of the South Medical Department, Sewanee, 1897; director and formerly vice president of the Citizens Bank of Waverly; died in St. Petersburg, Fla., February 10, aged 74, of leukemia and pneumonia.

Adela Jeanette Smith, New York; New York Homeopathic Medical College and Flower Hospital in New York in 1920; retired in 1943 after twenty-eight years as assistant director of health education in charge of the division of physically handicapped children in the city's public schools; died March 2, aged 74.

W. Edgar Smith, Dallas, Texas; Southern Methodist University Medical Department, Dallas, 1914; member of the American Medical Association; fellow of the American College of Surgeons; served during World War I; on the staff of St. Paul's Hospital; died February 2, aged 55, of coronary occlusion.

Albert L. Sparks, Springfield, Mo.; Ensworth Central Medical College, St. Joseph, 1906; also a druggist; died February 2, aged 69.

Paul Edward Spratlin, Washington, D. C.; Denver College of Medicine, 1892; died February 3, aged 85, of hypertensive heart disease.

Harry J. Stauffer, Jeannette, Pa.; Jefferson Medical College of Philadelphia, 1895; member of the American Medical Association; died February 2, aged 81, of cerebral hemorrhage.

Roy George Stevens ⊕ Sioux Falls, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; fellow of the American College of Surgeons; on the staffs of the McKennan and Sioux Valley hospitals; died February 20, aged 66.

Patrick Francis Strapp, Seymour, Conn.; Bellevue Hospital Medical College, New York, 1892; served as a member of the board of education; died February 5, aged 81.

Francis Leslie Sullivan ⊕ Scotia, N. Y.; Albany Medical College, 1924; fellow of the American College of Surgeons; *specialist certified* by the American Board of Surgery; member of the House of Delegates of the American Medical Association, 1944, 1945 and 1946; served on the staffs of the City, Ellis and the Eastern New York Orthopedic hospitals, all in Schenectady; died February 15, aged 50, of coronary thrombosis.

Gustavus Adolphus Sulzer, Columbus, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1892; died in Mount Vernon February 20, aged 78.

Charles Edward Taylor, Tacoma, Wash.; University of Oregon Medical School, Portland, 1897; formerly affiliated with the civilian conservation corps, Western State Hospital at Fort Steilacoom and the Eastern State Custodial School at Medical Lake; died in a local hospital February 5, aged 75.

William Girard Thompson, Enid, Miss.; Hospital College of Medicine, Louisville, Ky., 1894; member of the American Medical Association; died in the Grenada Hospital in Grenada, Miss, February 11, aged 74, of heart disease.

James Richard Tubman, Washington, D. C.; Columbian University Medical Department, Washington, D. C., 1895; member of the American Medical Association; died February 17, aged 79.

Edgar Lee West ⊕ Trenton, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1905; fellow of the American College of Surgeons; *served during* World War I; on the staff of St. Francis Hospital; died February 6, aged 67, of lymphosarcoma.

Walter Charles Wilhelmj ⊕ East St. Louis, Ill.; St. Louis University School of Medicine, 1904; past president of St. Clair County Medical Society; member of the American Urological Association; served as acting director of the East Side Health District; chief of staff, St. Mary's Hospital; affiliated with Christian Welfare Hospital; trustee and past president of the public library; died in Hot Springs, Ark, February 23, aged 65.

James Wallace Wilkes ⊕ Columbia, Tenn.; Cornell University Medical College, New York, 1900; past president of the Tennessee Otolaryngology Association; past vice president of the Tennessee State Medical Association; past president of the Maury County Medical Society; died February 19, aged 70, of heart disease.

Reuben Hamilton Williams, Moberly, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1916; member of the American Medical Association; served during World War I; *county coroner and city physician*; died February 6, aged 61, of coronary disease.

Howard Edwin Wright, Princeton, N. J.; University of *Pennsylvania Department of Medicine,* Philadelphia, 1893; medical inspector in the borough of Princeton public schools; member of the medical staff of Princeton University; medical adviser to private and parochial schools; on the staff of the Princeton Hospital, where he died February 18, aged 78.

COMDR. HAROLD E. STEDMAN
(MC), U. S. N. R., 1900-1945

CAPT EMMET ROBINSON SPICER
M. C., A. U. S., 1915-1945

LIEUT. (jg) JOSEPH A. MORTON
(MC), U. S. N. R., 1915-1944

KILLED IN ACTION

Harold Edwin Stedman, Garden City, N. Y.; University of Michigan Medical School, Ann Arbor, 1928; member of the American Medical Association and the American Urological Association; fellow of the American College of Surgeons; specialist certified by the American Board of Urology; interned at the U. S. Naval Hospital in Brooklyn; served a residency at the Jersey City Hospital in Jersey City, N. J., and the New York Hospital in New York; on the staffs of the Meadowbrook Hospital in Hempstead and the Nassau Hospital in Mineola; at one time an officer in the regular U. S. Navy; entered the medical corps of the U. S. Naval Reserve in November 1940 as a lieutenant commander; promoted to commander; died on the U. S. S. *Pinckney* April 29, 1945, aged 45, of wounds received in action.

Emmet Robinson Spicer, Goldsboro, N. C.; Cornell University Medical College, New York, 1941; interned at the John T. Mather Memorial Hospital in Port Jefferson, N. Y., and the Bellevue Hospital in New York; captain, medical corps, Army of the United States; killed in action in Corregidor Feb. 16, 1945, aged 29.

Joseph Anselm Morton, Rochester, N. Y.; University of Rochester School of Medicine and Dentistry, Rochester, N. Y., 1942; interned at the Genesee Hospital; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on July 1, 1943; killed in an explosion of Kamikaze plane Nov. 1, 1944, aged 29, while ministering to wounded seamen on deck of U. S. destroyer *Anderson* during the battle of the Philippine Islands.

The Birth Rate Reaches Replacement Level

A rise in the birth rate during the war and subsequently has been reported in The Journal from time to time, but the rate was always below the level of replacement—a fact which caused much concern to writers on the subject. Now at last it is announced that the replacement level was reached, for the first time in twenty-four years, in the last quarter of 1946. The deaths registered in that quarter for England and Wales numbered 122,173, representing a death rate of 11.3 per thousand of population, compared with 11.4 for the corresponding quarter of 1945. Deaths of children under 1 year of age numbered 9,139, giving a provisional mortality rate of 44 per thousand of related live births. This is 7 per thousand below the average of the ten preceding years 1936-1945. The "natural increase of population" (the excess of births over deaths for the quarter) was 99,718.

The number of persons married during the quarter numbered 191,256, which was 20,187 more than the average of the corresponding quarters of the preceding five years, 1941-1945. The birth rate for the whole of 1946 was 19.1 per thousand, the highest since 1923.

The approximate reproduction rate for the year was 1,102, which was 10 per cent in excess of that required to maintain the population. This is the first time that the rate has reached the replacement level since 1922, when the corresponding figure was 1,013. Infant mortality was the lowest ever recorded in this country, 43 per thousand, being 2 per thousand below that of 1944, the previous lowest.

A Medical Service for Students

A remarkable free medical service for students has been maintained by Edinburgh University for seventeen years. They are entitled to medical examination on admission and at other times when they wish. They are also encouraged to engage in physical education. Lately x-rays of the chest have been included in the examination. During the present year 752 (about 60 per cent) of the male students have been examined, and about the same proportion of women. Among the males 8 cases of pulmonary tuberculosis were found, the subjects being unaware of the existence of the disease. In addition to medical examinations, consultations are held three times a week for students wanting advice, and those unfit to attend can obtain domiciliary treatment. The medical service works in cooperation with the students' social service. It is devised for the benefit of those whose homes are not in Edinburgh. Local students are encouraged to use their family physician rather than the university medical service. The principal Edinburgh hospital, the Royal Infirmary, has a special students' ward. There is also a dental service organized through the Dental Hospital. It is hoped to have a university sick dormitory in one of the university hospitals, and a scheme for the full care of students suffering from tuberculosis is being considered.

The Perennial Character of Hughlings Jackson's Teaching

Of all the great men whose work is commemorated by lectures periodically delivered, Hughlings Jackson has a peculiar claim. His pioneer work in laying the foundations of neurology still remains unique. It is curious that, while neurologists are unanimous in his praise, none of them have attempted any work in his peculiar vein, though so much has been accomplished on other lines. Is this because he completely worked out that vein or because, though there have been many great neurologists, none have had the peculiar cast of mind required for work on Jackson's lines? This was simply the application of Herbert Spencer's philosophy of evolution to neurology. In the whole of medicine there is nothing comparable. Great teachers often indulge in philosophic reflections, but that is a very different thing from applying to medicine a definite philosophical system.

Permanence of Concepts

At the Section of Neurology of the Royal Society of Medicine the tenth Hughlings Jackson lecture was delivered by Professor E. D. Adrian, F.R.S. He began with a reference to Herbert Spencer as a philosopher who was today forgotten but who molded the thought of his Mid-Victorian generation and whose influence was shown in the development of neurology by his great admirer Hughlings Jackson. The theories and predictions of Hughlings Jackson were based on Spencer, and the illumination which they gave to neurology was as brilliant today as ever. Hughlings Jackson was one of the great clinicians of all time, a scientific observer of the first rank, and his theses were still fresh and individual and none the worse for our advancing knowledge. His ideas were cast in terms so general that they applied whatever the detailed structure of the nervous system might prove to be. Many of his writings were published before the neuron theory had been properly formulated. Most of the data of clinical neurology were available then as now, but he had not got our great mass of knowledge of cell structure and physiology. We now had no Spencer to give us an accommodating framework and no Jackson to fill in the picture, but we ought to survey our knowledge from time to time in the light of Jackson's theories.

Jackson described the evolution of the nervous system as proceeding from the lowest well organized centers to the highest least organized, from the most simple to the most complex, from the most automatic to the most voluntary. An example of low level complexity and the highest degree of organization was the stretch reflex. A higher level of complexity was shown in the flexion reflex in response to pain, in which the synaptic delay was twice as long as in the stretch reflex. The motor discharge was no longer confined to one pathway.

Pasteur Exhibition to Be Held in London

A Pasteur exhibition is to be held at the Science Museum, South Kensington, London, from April 10 to May 26. It has been arranged with the assistance of the cultural relations department of the French foreign office by the Palais de la Découverte in Paris, where it has recently been on show. It will include a chronological account of the chemical and biologic work of Louis Pasteur on fermentation, putrefaction, the spontaneous generation of life and the germs of numerous diseases in men, animals and plants. A section will deal with the Pasteur institutes established throughout the world for the preparation of serums and vaccines for the combating of epidemics.

Sir Joseph Barcroft

The physiologist Sir Joseph Barcroft, F.R.S., has died at the age of 74 years. After a distinguished career as a student and lecturer he became professor of physiology at Cambridge in succession to Langley in 1926. His researches on oxygen carriage in the blood are classic, and every student learns about his blood-gas apparatus, his oxygen dissociation curves and his classification of the varieties of anoxia. In a long controversy with the physiologist J. S. Haldane he maintained that the passage of gases through the alveolar epithelium of the lungs is a simple physical process and that even under adverse conditions the lungs cannot take up oxygen unless its pressure in the air is higher than that in the blood. In 1937 he retired from the Cambridge chair of physiology and, though already famous all over the world, at the age of 69 he entered a new sphere becoming director of the unit of animal physiology for the Agricultural Research Association. He introduced new technics for observing developing embryos and took up the problem of the oxygen supply of the fetus in utero. The first volume of his Researches on Prenatal Life has only recently been published. Most of the work was done on fetal sheep. There are experiments showing the variation in fats and sugars as between the maternal and fetal blood.

Vitamins in Aerosols in Treatment of Tuberculosis

Professor Léon Binet and H. Bour have used oxygenosols of vitamin D_2 in the treatment of serious pulmonary tuberculosis. Of 10 patients treated in this way, 6 (among whom were 2 with miliary tuberculosis and 1 with chronic phthisis in its terminal stage) did not respond. Four were obviously transformed. In the 4 patients the return of temperature to normal has been observed and by 2 the return to normal of the sedimentation rate. Cholesterol, which had diminished, regularly increased up to almost normal figures. Sputum diminished and became more fluid. On the whole, the inhalations of aerosols of vitamin D_2 have a general action, which enables the lesions to die away and then cicatrize. A mechanical therapy which could not be attempted previously becomes applicable After a previous observation of eight days the patient receives the first day one to two inhalations of 5 mg. of vitamin D_2 and then three inhalations per day, which are continued up to a total dose of 700 to 750 mg. The treatment therefore lasts about fifty days. The authors have used vitamin D_2 in an alcoholic solution. Every week, during treatment, they controlled the weight, the urea content and the calcium in the blood and urine; they also made a blood cell count and a differential leukocyte count.

Vitamin D_2 in Large Doses and Calcium Therapy in Tuberculosis of Adults

At one of the latest meetings of the Société des hôpiteaux médicale de Paris H. Gounelle and M. Bachet reported their results in the treatment by vitamin D_2 orally administered in pulmonary tuberculosis without renal deficiency. To large doses of vitamin D_2 the authors have added calcium and a diet rich in milk and its products. In 3 cases the evolution was obviously modified and the general condition remarkably improved. In 2 patients, surgical intervention could be considered and in the third the important cavities have disappeared. On the first sign of hypervitaminosis, clinical as well as humoral, the treatment is to be interrupted; the authors confirm that the calcemia generally precedes azotemia; the intramuscular route is best tolerated, but its efficacy is still under study.

A New French Medical Society

A French medical society of pathology of the respiratory system has just been created at the suggestion of Dr. Ameuille of Paris. Its aim is the study of nontuberculous illness of the respiratory system. The organ of the society will be the *Journal français de médecine et de chirurgie thoraçique.*

The twenty-sixth Congress of Medicine will take place in Paris on the 16th, 17th and 18th of October under the presidency of Professor Lemierre. The program will include papers on genetics, antihistaminics and cysts of the lungs.

Death of Pierre Janet

Professor Pierre Janet, psychiatrist, has died at the age of 87. Together with Freud, he had been a disciple of Charcot. He was the author of classic works on psychiatric automatism, hysteria, neurosis and fixed ideas; we are indebted to him for our ideas concerning psychasthenia.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, April 12, 1947.

Immunity in American Trypanosomiasis

Drs. Julio Muniz and Gilberto de Freitas, from the Oswald Cruz Institute, Rio de Janeiro, reported results of serologic tests on samples of blood serum from 6 cases of acute trypanosomiasis (Chagas' disease) and from 211 chronic cases. With this material they undertook to advance the study of humoral immunity in the disease.

The serums from the 6 acute cases obtained at different times after onset of the infection (fifteen to forty days) strongly fixed the complement in titers varying from 1:40 to 1:160. The agglutinating strength of the serums from the acute cases varied between the titers of 1:2,560 and 1:20,000, and they all strongly reacted in the precipitation test (ring test) within ten minutes. The precipitation test proved positive every time the serums agglutinated at a titer higher than 1:640. About 80 per cent of the serums from the chronic cases were able to fix the complement at the dosage of 0.05 Gm. at varying intensity. Included in this total was a case in which the infection dated back more than thirty years. In 85 per cent of those cases an agglutinating strength was registered in titers varying from 1:160 to 1:2,560. The precipitin reaction (ring test) was positive in 18 per cent of the cases. The serum from the patient whose infection dated back more than thirty years agglutinated at the titer of 1:640.

Inhibitory Action of Phenol on Histamine

Dr. Celso Barroso, director, São Paulo Institute for Allergy, has published a report on his experimental and clinical study on the inhibitory action of phenol on muscle contraction induced by histamine injection. In 1943, when Barroso attempted, with the collaboration of Rocha e Silva, the passive transference of antibodies from man to guinea pig, as had been proved possible by others, he failed to obtain similar results. One explanation for failure was supposed to be the presence of phenol in the Coca's solution used. This fact led the author to perform studies which proved conclusively that phenol should be included among the substances with inhibitory action on the contraction of plain muscles induced by histamine. When previously added to Tyrode's solution that bathes isolated portions of guinea pig intestine, phenol inhibits the toxic effects of histamine. When added to the same solution in which there is a fragment of guinea pig ileus already contracted by the effect of histamine, phenol causes the immediate and total relaxation of the organ, comparable to a similar effect obtained by the use of epinephrine or atropine. An important point disclosed by Barroso's experiments is that phenol cannot inhibit vasodilatation caused by histamine. An intradermic injection of a mixture of histamine and phenol acts like an injection of a pure solution of histamine, causing the same vasodilatation. Barroso was able to verify that it is possible to increase the therapeutic action of epinephrine in relation to its power of dilating the brochioles in asthmatic patients by the addition of phenol to the drug.

Death of Afranio Peixoto

Dr. Afranio Peixoto, professor emeritus, University of Rio de Janeiro, died at the age of 67. After graduating from the Medical School of Salvador, state of Bahia, he moved to Rio de Janeiro, where he was to begin a remarkable career as professor of hygiene. He published many scientific essays and several novels, which were all best sellers. He was a member of the National Academy of Medicine and also one of the forty members of the Brazilian Literary Academy. His death was a great loss to medicine and to Brazilian letters as well.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, May 10, page 209.

BOARDS OF MEDICAL EXAMINERS

Alabama: Montgomery, June 24-26. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

Arizona: *Examination.* Phoenix, July 1-2. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

Arkansas: * *Medical. Examination.* June 5-6. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 5. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Written.* San Francisco, July 7-10. *Oral.* San Francisco, May 10-11. *Oral Clinical Examination for Foreign Medical Graduates.* San Francisco, June 21. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Colorado: *Examination.* Denver, July 18. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

Connecticut: *Examination.* Hartford, July 8-9. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, July 8. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

Delaware: *Examination.* Dover, July 8-10. *Endorsement.* Dover, July 15. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia: * *Reciprocity.* Washington, June 9. Sec., Commission on Licensure, Dr. George C. Ruhland, 6012 E. Municipal Bldg., Washington 1.

Florida: * *Examination.* Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

Georgia: Atlanta, Oct. 14-16. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Hawaii: *Examination.* Honolulu, July 8-11. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, July 14-16. Sec., Bureau of Occupational Licenses, Dr. S. M. Poindexter, Eastman Bldg., Boise.

Illinois: *Examination.* Chicago, June 24-26. Sec., Mr. Philip M. Harman, Supt. of Registration, State House, Springfield.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Kansas: *Endorsement.* Kansas City, June 26. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

Kentucky: *Examination.* Louisville, Sept. 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Maine: Augusta, July 1-2. Sec., Board of Registration in Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Medical Examination.* Baltimore, June 17-20. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 10-11. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Massachusetts: *Examination.* Boston, July 8-11. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston.

Michigan: * *Examination.* Detroit, June 9-11. Semi-Annual meeting, Lansing, June 24. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Minnesota: *Examination.* Minneapolis, June 17-19. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: Jackson, June 23-24. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

Missouri: *Examination.* St. Louis, May 26-28 and June 9-11. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Building, Jefferson City.

Nebraska: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

New Hampshire: *Examination.* Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, June 23-26. Sec., Dr. Jacob L. Lochner Jr., State Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, June 24. *Examination.* Raleigh, June 23-26. Acting Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, June 17-20. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma: *Examination.* Oklahoma City, June 3-4. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Pennsylvania: Philadelphia and Pittsburgh, July. Acting Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, June 23-25. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * Pierre, July 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Tennessee: Memphis and Nashville, June 11-12. Sec., Dr. Harley W. Qualls, 1635 Exchange Bldg., 130 Madison Ave., Memphis 3.

Texas: Austin, June 5-7. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Building, Dallas 2.

Virginia: Richmond, June 18-21. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., 30½ Franklin Rd., Roanoke.

West Virginia: *Examination.* Charleston, June 30, July 1-2. Commissioner, Public Health Council, Dr. Newman H. Dyer, State Capitol, Charleston 5.

Wyoming: *Examination.* Cheyenne, June 2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: June 17. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: Denver, June 4-5. Sec., Dr. Esther B. Starks, 1459 Ogden Street, Denver.

Connecticut: June 14. Exec. Asst., State Board of Healing Arts, Mr. W. G. Reynolds, 250 Church St., New Haven 10.

Iowa: Des Moines, July 8. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Minnesota: Minneapolis, June 3-4. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Oregon: June 7. Final date for filing application is May 21. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

South Dakota: Vermillion, June 6-7. Sec., Dr. G. M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Nashville and Memphis, June 13-14. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Medical Motion Pictures

NEW MOTION PICTURE ADDED TO A. M. A. FILM LIBRARY

A Stitch in Time. 16 mm., black and white, sound, 900 feet (one reel), showing time twenty-five minutes. Sponsored by the Sears-Roebuck Foundation and endorsed by the National Safety Council. Produced in 1944 by C. L. Venard, Peoria, Ill. Procurable on loan from Motion Picture Library, American Medical Association, 535 North Dearborn Street, Chicago 10.

Farming today is one of the most hazardous of all occupations. Many industries are compelled by law to provide safety devices for their employees and to provide care and compensation for any one who is injured. Generally the farmer is his own boss or employs only a few men. As a rule he does not carry compensation, hospital or accident insurance. He is, however, handling machinery that is just as powerful as many other industrial machines and handling the machinery over rough ground in contrast to many industries that can bolt the machine securely to a solid floor. The National Safety Council estimates that more than 1,500,000 rural people are injured annually. Safeguarding the health of rural people is of special importance not only to rural people themselves but also to the entire nation.

The motion picture "A Stitch in Time" is designed to make the American farm a safe place to work and live. It brings out vividly the peacefulness and beauty of the countryside and then awakens us to the many hazards that are lurking unseen in all this serenity. The picture stresses the importance of self protection through education and preventive methods. The country doctor whom the farmer summons to save his little girl from the venomous snake attack clearly shows the importance of a widespread safety program by every person. Farmers are not more careless than other people but from pioneer days they learned to be fearless and courageous and perhaps take many chances that could be easily avoided.

This film is highly recommended for showing before all rural groups as an educational project in extending better health to rural communities.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Charitable Hospitals: Right of Employees to Organize and Bargain Collectively.—The Laundry Workers, Dry Cleaners and Miscellaneous Workers of the Amalgamated Clothing Workers of America petitioned the labor relations commission for certification as the collective bargaining agency of certain nonprofessional employees of St. Luke's Hospital. The hospital filed a motion to dismiss on the ground that the commission had no jurisdiction to entertain the petition. Before the commission made a ruling on such motion, however, the hospital filed the present proceeding asking for a declaratory judgment that the commission had no jurisdiction to hear the petition for certification. In this action a preliminary injunction was issued restraining the commission from taking any further action in the certification proceedings, so the commission appealed to the Supreme Judicial Court of Massachusetts.

The hospital was incorporated in 1884 as a nonprofit, charitable corporation. It has more than 300 beds and maintains an outpatient department and various clinics. Its funds are obtained from fees, gifts, bequests and participation in a local community fund. It furnishes free services to patients who are unable to pay, and such service amounted in 1945 to 12 per cent of the total service rendered by the hospital. Treatment and care of recipients of city welfare are paid for by the city at a rate less than the regular charge. The federal government pays for services provided for federal patients. The union sought certification as the bargaining agent of 125 employees, including laundry workers, maids, porters, machinists, yard help, watchmen, storemen, waitresses, page girls, kitchen and cafeteria help and orderlies.

The only question of substantive law presented is whether or not the hospital comes within the sweep of the state labor relations act. The policy of that act, said the court, is the promotion of peace and the prevention of strikes in order that there may be no obstructions to the free flow of industry and trade. To come within the ambit of the authority of the commission, the selection of a bargaining representative must be connected with and related to industry and trade. A hospital like the plaintiff, whose doors are open to those needing medical and surgical treatment for which no charge is made to those unable to pay, which depends for its support and maintenance on fees, gifts and donations, which cares for recipients of public welfare at reduced rates and which is conducted in the interests of the general public and strictly as a nonprofit organization is a public charity. Such a hospital, said the court, is not conducting a business or commercial enterprise and is not engaged in industry and trade. Continuing, the court pointed out that the agreed facts showed that the sole activity of the plaintiff is the maintenance of its hospital and that the services of its nonprofessional employees, for whom the union seeks certification as their bargaining agency, are directed to that end.

It is urged by the commission, however, that a hospital comes within the definition of an "employer," because the word as defined in section 2 includes "any person acting in the interest of an employer, directly or indirectly, but shall not include the commonwealth or political subdivision thereof, or any labor organization," with certain exceptions. It is contended that, specific exceptions having been expressly mentioned, no others may be supplied by implication. This contention, said the court, rests on a familiar principle of statutory interpretation. But the entire chapter in which the definition appears must be construed as a whole, and the question is not whether a hospital is expressly exempted but whether a hospital comes within the sweep of the chapter in the light of its declared underlying and predominant aim and object. It is true, said the court, that the employees whom the union sought to represent were engaged in various kinds of manual labor, some of which were similar to those performed in hotels. It is also true, continued the court, that such services were essential to the maintenance of the hospital. Those rendering the services, however, can hardly be said to be engaged in industry or trade. The policy limits the scope of the act and clearly shows that a hospital which is organized and conducted as a public charitable institution is not covered by the act. Accordingly the order granting the preliminary injunction was affirmed and a final decree entered adjudging that the hospital and its nonprofessional employees engaged in duties necessary for the maintenance and operation of the hospital are not within the provisions of the state labor relations act.—*St. Luke's Hospital v. Labor Relations Commission, 70 N. E. (2d) 10 (Mass., 1946).*

Malpractice: Death Following Tonsillectomy—Application of Res Ipsa Loquitur.—The plaintiff sued for damages because of her daughter's death following a tonsillectomy, the death allegedly having been caused by the negligence of the defendant physician. From a directed verdict in favor of the defendant, the plaintiff appealed to the Supreme Court of Mississippi.

The defendant performed a tonsillectomy on the plaintiff's child. After the operation the child was returned to her hospital bed, at which time the defendant told the plaintiff to go out and get some lunch, "the baby is all right." The plaintiff returned about twenty minutes later and noticed that the child appeared abnormal. The defendant was immediately called. He felt her pulse and at once summoned other doctors and the nurses. Oxygen was administered without favorable results and the child died in a very short time. The only witness at the trial was the plaintiff. At the conclusion of her testimony the defendant physician moved the court "that there be a directed verdict in favor of Dr. Smith for the reason that there has been no proof offered of any lack of care and skill . . . all that has been introduced is the fact that he operated on the child, and the child died." The motion was sustained by the trial court in a brief statement that "our courts have held, in the *Berryhill v. Nichols* case, and in subsequent cases, that to establish liability for a wrongful death there must be a believable probability rather than a possibility; . . ." On appeal to the Supreme Court, the plaintiff contended that she was entitled to the benefits of the doctrine of "res ipsa loquitur," saying "It is a matter of common knowledge that death does not ordinarily result from a tonsillectomy. Yet, Evelyn Sanders died shortly after a tonsillectomy was performed on her. Why she did so, neither we nor [appellees] know. We submit that her parents are entitled to an explanation. And that the court erred in excusing [appellees] from making such explanation."

In a prior Mississippi case the Supreme Court said "Res ipsa loquitur means that the facts of the occurrence warrant the inference of negligence; not that they compel such an inference, but that they furnish circumstantial evidence of negligence where direct evidence of it may be lacking." After discussing a number of cases from other jurisdictions in which the principle of res ipsa loquitur was involved, the Supreme Court said that it had previously laid down the rule that the doctrine of res ipsa loquitur should be cautiously applied. An analysis of the cases, continued the court, leads to the conclusion that the test is not that the result of the operation was unusual and unexpected, or even fatal, alone and by itself. The real question is whether or not in the process of the operation any extraordinary incident or unusual event occurred outside of the routine of the action of its performance and beyond the regular scope of customary professional activity in such operations, which, if unexplained, would itself reasonably speak to the average man as the negligent cause or causes of the untoward consequence. If there were such extraneous interventions, then the doctrine of res ipsa loquitur would be applicable to call on the defendant to explain the matter by evidence of exculpation if he could. The jury would then decide the issue of fact in the case. In the case at bar, however, the court concluded, we are of the opinion that the maxim has no proper application and that the trial court was correct in entering a directed verdict for the defendant. The judgment of the trial court was accordingly affirmed.—*Sanders v. Smith, 27 So. (2d) 889 (Miss., 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Experimental Carcinoma of Gallbladder: Supplementary Data. N. N. Petrov and N. A. Krotkina.—p. 241.

Phenylpropanolamine Hydrochloride for Maintaining Blood Pressure During Spinal Anesthesia.—Phenylpropanolamine hydrochloride was used in 263 cases after the administration of a spinal anesthetic. Its ability to maintain blood pressure during the performance of a variety of surgical procedures has been established. The drug is an effective vasopressor agent with a moderately prolonged action—forty-five minutes—and has no apparent harmful side effects. The optimal effective dose of phenylpropanolamine hydrochloride was found to be 50 mg. administered intramuscularly. This dose maintained the blood pressure at preoperative levels in 90 per cent of the cases studied. Phenylpropanolamine hydrochloride has a vasopressor effect which compares favorably with the action of epinephrine, ephedrine and neosynephrine and offers certain advantages over them; namely, a more prolonged action and less frequent excitation.

Streptomycin in Surgical Infections.—One thousand cultures of bacteria were tested for their susceptibility to streptomycin by a broth-serial-dilution method. Pulaski and Sprinz present data on results of studies on absorption, distribution and excretion of streptomycin in the body following parenteral administration of the drug. The results of susceptibility tests and of assays of blood serum concentrations of streptomycin have been correlated, and on this basis a division is made between clinically sensitive and clinically refractory bacteria.

Sympathectomy in Trench Foot.—Shumacker and Abramson say that of 700 cases of trench foot at the vascular center at the Mayo General Hospital sympathectomy was done in 49. Sixty-six lower extremities were sympathectomized. The second and third lumbar sympathetic ganglions with the intervening chain were excised through an anterior extraperitoneal approach. In many cases the operation was preceded by a procaine lumbar sympathetic block. The chief indications for operation are (1) extensive gangrene, (2) excessive sympathetic tonus and (3) the complaint of pain on weight bearing. Sympathectomy accelerated healing in cases of extensive gangrene associated with vasospasm. It was also of aid in treating the maceration of the skin and the complicating secondary infection which result in the event of prolonged hyperhidrosis. The procedure reduced the severity of the symptoms in cases in which cold sensitivity was present. It produced variable results in the treatment of pain on weight bearing but had some therapeutic effect on the sensory disturbances. Sympathectomy has a definite but limited use in certain selected cases of trench foot. It appears to have no applicability in the majority of cases.

Penicillin in Treatment of Keratosis Blennorrhagica with Polyarthritis. A. W. Freireich, S. Schwartz and O. Steinbrocker.—p. 239.

Nutritional State and Atherosclerosis.—In a comparison of the incidence of various degrees of general atherosclerosis and of atherosclerosis of the coronary arteries at necropsy of 395 obese persons, 372 persons of average nutrition and 483 poorly nourished persons 35 years of age and older, Wilens found that advanced atherosclerosis is about twice as common in the obese as in the poorly nourished group. The group with average nutrition has less severe atherosclerosis than the obese group but more than the poorly nourished one. The relationship demonstrated between the state of nutrition at necropsy and the degree of atherosclerosis is independent of age, sex, hypertension, heart weight and diabetes. Obesity appears to be a more striking factor in the development of atherosclerosis in men than in women. This is particularly true of atherosclerosis of the coronary arteries. Although the analysis is based on the state of nutrition as observed at necropsy, evidence is presented to show that if the analysis had been based on the probable state of nutrition prior to the onset of the final illness the relationship between atherosclerosis and nutrition would be even more striking.

Induced Malaria.—Engstrom and his associates made attempts to transmit Plasmodium vivax malaria in 195 patients with neurosyphilis by mosquito bites or by inoculation of blood. The strains transmitted were of Pacific and Mediterranean origin. The attempts to transfer P. vivax malaria by mosquito bites or by inoculation of blood were highly successful in white patients, whether they gave a past history of malaria or not, and relatively unsuccessful in Negro patients. A spontaneous remission of fever was observed more than three times as frequently in those who gave a past history of malaria as in those who did not. The prepatent and incubation periods averaged about two weeks when mosquitoes, and five days when blood, was used in the transmission of the infection. As the disease progressed the concentration of parasites in the blood at first rapidly increased but after the eleventh day began to fall. Sixty-five per cent of the patients inoculated by mosquitoes infected with Pacific strains of P. vivax had relapses, while no patients relapsed who had been inoculated intravenously with blood containing the same strains. Quartan malaria was transmitted to 48 patients (45 Negro and 3 white) by inoculation of blood containing P. malariae. Quartan malaria differed from tertian (*P. vivax*) malaria not only in the longer interval between paroxysms but also in the longer period of incubation, the slower response to quinacrine therapy and the tendency to cause serious renal complications.

Cyclopia. S. Gartner.—p. 220.

Removal of Foreign Bodies from the Cornea.—Fox reports the results of observations on 6 deeply embedded corneal foreign bodies which required removal. The foreign bodies were all metallic. Three were found to be magnetic after removal. Even if the foreign body is magnetic, the magnet is useless in removal of these deeply embedded bodies from the cornea until they have been loosened from the surrounding stroma. In all 6 cases the cornea was healed within four days or less. Clean incision of the cornea, instead of "picking" at it, results in less mutilation of corneal stroma and consequently less corneal opacification. If the cornea should be penetrated, the flap is an efficient valve with which the anterior chamber can be sealed off instantly, and it heals in rapidly.

Arachnoiditis.—Kravitz points out that arachnoiditis is either adhesive or cystic in form. The cysts are collections of cerebrospinal fluid walled off by adhesions, and the fluid may at times be under great tension. The adhesive form is characterized by dense adhesions, which may bind the optic nerves and chiasm to any or all of the surrounding structures. The optic nerves and chiasm are usually involved in the opticochiasmic type of the disease. In this form of arachnoiditis sight is frequently jeopardized and the disks are rarely normal. There may be primary, secondary or a segmental type of atrophy of the optic nerve, or even extreme degrees of choked disk, or any combination or gradation of these signs. A central scotoma is common. Occasionally one sees typical bitemporal field defects, but more often they are bizarre. The most usual symptom in this form of arachnoiditis is the early, and usually rapid, loss of vision. The prognosis is good, especially as regards vision, if operation is resorted to early. If the condition has lasted too long, the loss of vision becomes irreparable. If conservative treatment fails, operative treatment is advisable. The author reports 9 cases and stresses that arachnoiditis is not as rare as is commonly thought. Opticochiasmic arachnoiditis presents a great threat to vision, but other forms of arachnoiditis can be as great a threat.

Reactions of Monkeys to Mixed Influenza and Streptococcic Infections.—Wilson and his associates report studies on monkeys which were infected with influenza and streptococci either simultaneously or in varying sequence. They demonstrated the vital importance of the cellular defense forces in the resistance of the monkey to combined streptococcic and influenza virus infections. Some of the conditions prejudicial to the maintenance of an optimum cellular reserve in the infected animal were undernutrition, physical cold and the intratracheal route of infection. The potential threat exerted by latent foci of streptococci and the combined infection with virus have been demonstrated. Optimum nutrition, notably as concerns the vitamin B complex and folic acid, specifically plays an important part in the prevention of disastrous illness from these infectious agents. Simultaneous intranasal inoculation of influenza virus type A and Streptococcus hemolyticus group C in nutritionally normal Macaca mulatta failed to produce obvious signs of disease. In most of the animals a streptococcus induced leukocytosis developed followed by a delayed virus induced granulopenia. The development of signs of infection in previously healthy monkeys exposed to virus followed by streptococci confirms both clinical and laboratory experience of other observers that virus infection may predispose to secondary bacterial invasion and that the infection may become overwhelming.

Tetanus. N. Silverthorne.—p. 195.

Rheumatic Pneumonia.—Mossberger thinks that since acute rheumatic fever is predominantly a childhood disease, and because most of the heart disease in children is rheumatic, the possibility must be considered that the pneumonia which occasionally develops in a child with endocarditis is also rheumatic in origin. Jensen has pointed out that probably many of the "primary atypical pneumonias" that have formerly been observed in cases of rheumatic fever were in reality rheumatic or poststreptococcic pneumonitis. Two cases of "atypical" pneumonia developing in the course of rheumatic fever are presented by Mossberger. Together, these 2 cases of lung disorder in children with rheumatic heart disease show most of the features of an exudative lesion resulting from injury to the capillary endothelium. Pulmonary histopathology parallels that seen in experimental and sulfonamide anaphylactic pneumonitis. The clinical histories of the 2 patients are consistent with the concept of an allergic mechanism in the production of pulmonary disease and stress that an exudative reaction such as pneumonitis may be delayed for some time after symptomatic subsidence of the initial endocarditis. This thought must be borne in mind in all cases of sulfonamide-penicillin resistant pneumonia occurring in children with histories of rheumatic fever.

Salicylate Intoxication in Young Children.—Most of the 13 patients with salicylate intoxication reviewed by Erganian and her associates were infants who received aspirin (acetylsalicylic acid) as treatment for a "cold." Studies on these 13 patients included salicylate concentration of the blood plasma and spinal fluid, p_H of the blood serum, carbon dioxide content of the serum, prothrombin time and urine examination. Other laboratory studies included serum chloride, glucose and nonprotein nitrogen determinations. The most severe type of reaction occurring in this group is a disturbance of the acid base equilibrium. At the time of hospitalization, all patients showed a metabolic acidosis with a lowered p_H and carbon dioxide content of the serum. Salicylates given experimentally to older children whose usual caloric and liquid intake were maintained produced less regular, if any, signs of toxicity. Salicyl compounds, when given in dosages from 0.066 Gm. per kilogram in twenty-four hours in six divided doses (approximately ½ grain per pound), tend to accumulate in the body, as shown by determinations of plasma levels. In view of the dangers and possibility of fatality in infants, it is suggested that aspirin be given not at all or very cautiously.

Acute Glomerulonephritis.—Burke and Ross review the salient clinical feature of 90 consecutive cases of acute glomerulonephritis observed at the Children's Hospital during the past three years. Eighty-four of the 90 patients recovered, 3 died during the acute attack and 3 developed chronic glomerulonephritis. The three deaths were associated with or were the direct result of acute nephritic congestive heart failure. Acute glomerulonephritis has been the most common cause of congestive heart failure at Children's Hospital for the past three years and was present in 35 of the 62 patients with acute nephritis who were examined for evidence of this complication. The treatment consisted largely of absolute bed rest and the management of symptoms as they appeared. The author stresses the advisability of administering digitalis in all cases of acute nephritis complicated by congestive heart failure.

Squamous Cell Carcinoma of Renal Fossa.—A man aged 38 had hematuria for fifteen years until January 1945. At that time the left kidney was removed for calculous disease. A large stone was found in the renal pelvis, but there was no microscopic study done on the kidney. In July 1945 the patient injured his left side and began having pain in that area. He became depressed and was transfered to a mental hospital for "shock treatments." He continued to complain of pain. Tentative diagnoses were made of retroperitoneal hematoma, retroperitoneal abscess and retroperitoneal sarcoma. Sections of tissue removed at operation led to the diagnosis of squamous cell carcinoma of the kidney. Madison says that Kretschmer pointed out in 1917 the influence of chronic infection and calculi on squamous cell carcinoma of the renal pelvis. The mental attitude of this patient was due to the toxic state, for even in the short period following drainage his attitude improved considerably.

Hypertension Due to Unilateral Renal Disease.—A woman aged 48 was taken sick suddenly with symptoms and signs of severe hypertension. She had impairment of vision in both eyes. Urologic examination revealed a very small right kidney lacking any degree of function. Nephrectomy resulted in a complete cure, including return of vision and decrease of blood pressure to normal. The patient's condition continued normal until ten months after operation, when very stormy symptoms and signs of acute cardiorenal failure developed. Death occurred eighteen days later of uremia. Crosbie and Fischmann believe that this case is worthy of being reported as another disappointing trial of surgical treatment for hypertension caused by renal disease.

Hemorrhage Following Suprapubic Prostatectomy.—According to Wilhelm and Levine, suprapubic prostatectomy is still widely practiced for the relief of the larger benign hypertrophies. In 400 consecutive suprapubic prostatectomies for nonmalignant hypertrophy carried out at the Beth Israel Hospital there were 20 postoperative hemorrhages severe enough to require surgical intervention (5 per cent). When packing with gauze strips was done the incidence was 3.5 per cent, as compared with 13.1 per cent in the patients in whom a Foley catheter was used. Patients with a Foley catheter bled most frequently immediately after operation, whereas hemorrhage occurred most often in the early secondary period when gauze packing was used within twenty-four hours after removal of the packing. Delayed secondary bleeding occurred in 5 cases, on from the sixth to the seventeenth postoperative day and was caused by straining at stool, coughing, alkaline cystitis and residual prostatic tissue. The mortality rate of the patients suffering from hemorrhage was 15 per cent, as compared to the general rate of 2.75 per cent. None of these patients died of exsanguination. Postoperative hemorrhage and infection were the chief complications contributing to the mortality rate.

*Benadryl for Ivy Poisoning: Preliminary Report on Its Use in 14 Cases. L. S. Blumenthal and M. H. Rosenberg.—p. 86.

Benadryl for Ivy Poisoning.—Blumenthal and Rosenberg employed benadryl in treating 14 patients with ivy dermatitis. Most of the patients received local therapy for several days before the institution of benadryl treatment. Four of the patients continued to use the local medication after onset of benadryl treatment. Twelve of the 14 patients experienced great relief from the associated pruritus from four to eight hours after each dose. These patients could be maintained symptom free on 50 mg. doses of benadryl orally every four to six hours. Two patients received moderate relief. The lesions stopped spreading soon after the beginning of treatment in 3 patients and entirely cleared within seventy-two hours. The treatment did not alter the usual course of the rash in the other 11 patients even though the pruritus was controlled. The action of benadryl in these cases lends support to the theory that a histamine-like substance is liberated at the site of skin irritations.

Sickness Absenteeism Among Industrial Workers, Second and Third Quarters of 1946. W. M. Gafafer.—p. 272.

Restaurant Sanitation.—Fuchs discusses the importance of restaurant sanitation, pointing out that the Public Health Service acts solely in an advisory and stimulative capacity. It leaves enforcement to state and local health authorities. In a previous report the author outlined the development of the ordinance and code regulating eating and drinking establishments recommended by the United States Public Health Service. The current edition of the ordinance and code was printed in 1943 as Public Health Bulletin number 280. It is the culmination of nine years' effort, representing five different drafts. It is subject to change as improvements are developed. For the past three years the Public Health Service has devoted major attention to the portion of its restaurant sanitation program concerned with the education of food handlers. Sanitarians interested in organizing food handler schools in their communities may apply to their state health department and to the district office of the Public Health Service for assistance.

Intracranial Aneurysms: Considerations in Surgical Management. J. G. Galbraith.—p. 139.
Carotid Body Tumor. R. H. Smoot.—p. 159.

Malignant Melanoma in Negro.—A total of 73 cases of malignant melanoma in the Negro have been recorded, and these with the 6 cases presented by the authors make a total of 79 cases. One of the 6 reported cases is the second instance of a primary lesion developing in the nose, 1 is the third reported case of a malignant melanoma occurring in the mouth and another is the first instance of a primary lesion in the rectum. In 2 other cases the primary sites were the plantar surface of the great toe and the skin of the back. In 1 case it was impossible to determine the site of the primary lesion.

Whole Skin Grafts for Inguinal Hernia.—Goodall and Guthrie describe the successful repair of 6 inguinal hernias by the use of whole thickness skin grafts. The grafts were excised from the abdominal wall over the hernia site and implanted over the floor of the inguinal canal. The types of inguinal hernias repaired included 3 indirect inguinal hernias, 1 direct inguinal hernia, 1 sliding hernia of an indirect type and 1 recurrent saddle bag type hernia following a previous modified Bassini repair three and one-half years previously.

Paralytic Ileus.—Devine presents the results of a clinical study of a number of cases of paralytic ileus, of 43 cases in which intestinal intubation with the Miller-Abbott tube was performed, of a number of observations on patients with ileostomies and jejunostomies and of x-ray observations. True or idiopathic postoperative paralytic ileus is rare. It is a dangerous diagnosis to make, for it often prevents recognition of the real cause till it is too late for appropriate treatment. It was found that heat or turpentine stupes on the abdomen had no effect on bowel movements. Barbiturates decreased peristalsis and tone. Penicillin and sulfonamides did not materially affect peristaltic movements. Overdistention of the stomach caused loss of tone and decreased movement of the small bowel. Stimulation of the large intestine by enemas also stimulated the small intestine, even when this was completely isolated from the colon. By far the most frequent cause of a postoperative ileus is a postoperative intra-abdominal infection. From a study of Miller-Abbott recordings and abdominal sounds with regard to the return of intestinal movements after operation, and the return of these movements during recovery from paralytic ileus, the author deduces that there are three phases of ileus: stage 1, in which the movements are active, coordinated, responsive to stimulation and effective; stage 2, when they become irregular, incoordinated and are ineffective, and stage 3, fully developed paralytic ileus, when the intestinal movements disappear and completely fail. Stimulation in the second stage will often precipitate a paralytic ileus.

Liver Extract, Folic Acid and Thymine in Anemia.—Spies and Stone gave folic acid to 9 patients with subacute combined degeneration and synthetic thymine to 4 patients with pernicious anemia. The effect of refined liver extract is also illustrated on the basis of a case report. The authors conclude that synthetic folic acid (Lactobacillus casei factor) and synthetic thymine (5-methyl uracil) will neither prevent the development of subacute combined degeneration in addisonian pernicious anemia nor relieve it once it has developed. Frequent parenteral injections of a potent liver extract are useful in the prevention of subacute combined degeneration and beneficial in relieving it once it has developed.

Sulfonamides in Acute Inflammation of the Middle Ear.—According to Lüscher and Iselin 606 patients with acute inflammation of the middle ear and its complications were admitted to the ear, nose and throat clinic of the University of Basle during the period of 1937 to 1940, when systematic sulfonamide treatment was not yet instituted. Five hundred and five patients with acute inflammation of the middle ear, acute recurrence mastoiditis and otogenous intracranial complications were admitted during the period of 1941 to 1944, when systematic sulfonamide treatment was practiced. The frequency of surgical intervention in the clinic decreased by 32 per cent during the second period as compared with the first; in the majority of the cases prevention of mastoiditis accounted for this decrease. There was a decrease in intracranial complications of the acute ostitis from 10.5 per cent during the first period to 4.2 per cent during the second period, but this applies almost exclusively to epidural abscess. There was a decrease of only 3.5 per cent to 3.3 per cent in the severe complications, including leptomeningitis. Mastoiditis proved chemoresistant in almost all the cases. Chemotherapy appears to be contraindicated in the presence of symptoms of mastoiditis. Mortality of acute otitis media has been reduced from 2.1 per cent to 0.79 per cent, and that of chronic suppurative otitis media from 2.6 per cent to 1.5 per cent. The total mortality of otitis media has been reduced from 2.2 per cent to 0.9 per cent. Systematic treatment with sulfonamides in home practice is suggested for all grave cases of acute inflammation of the middle ear.

Problem of Generator Gas Intoxication: III. Differential Diagnostic Points of View Regarding Acute and Chronic Carbon Monoxide (Generator Gas) Intoxication. G. Wohlfahrt, B. Gullberg and A. Svensson. —p. 2726.

Generator Gas Intoxication.—Forssman says that generator gas contains from 20 to 30 per cent of carbon monoxide, which is the toxically active constituent in generator gas. The generator gas problem is thus from the medical and hygienic points of view identical with the carbon monoxide gas problem. Chronic intoxication, the existence of which is questioned by some, may be mainly a sequel of repeated slight acute intoxication. Experiments in animals seem to confirm this theory. The sensitivity to carbon monoxide is variable in normal persons. It may be changed either to hypersensitivity or to tolerance by exposure to the gas.

Book Notices

Crippled Children in American Education, 1939-1942. By Romaine Prior Mackie, Ph.D. Teachers College, Columbia University Contributions to Education, No. 913. Cloth. Price, $2.10. Pp. 144. Bureau of Publications, Teachers College, Columbia University, 525 W. 120th St., New York 27, 1945.

This volume collects facts and figures which of themselves can be of little value to one interested in the education of the handicapped. The figures cover a small area of the country. About 25,784 out of a possible "more than 100,000" (p. 3) children are being educated according to figures found in the introduction; this survey covers only 16,696 children of a few schools, mostly in New York, New Jersey, Maryland, Michigan and Ohio. Little mention is made of Chicago, where education of the crippled child occupies an important place in the special school system. Early diagnosis and emergency treatment of poliomyelitis, once the disease which led all others in crippling effects, today rates about third on the list, both spastic paralysis and cardiac cases ranking first and second. The survey demonstrates the great differences of opinion among educators of the East as to where and how the handicapped shall be educated. This difference will always exist as long as each city or state selects its own plan of education rather than following the same plan as for physically fit children. The high school situation and the advantages offered by state rehabilitation funds for college or advanced educational work seem to be neglected, though in Chicago a definite setup for this educational phase has been in vogue for many years. Chapter IV gives to the layman a short concise description of each of the so-called crippling causes. Table IV of this chapter presents a picture which one could not visualize without the statement of facts contained therein. The table on distribution according to race cannot be considered too seriously, since the Southern states have most Negroes, and specialization in the care of handicapped in those regions is neglected. Statements to the effect that "most crippled children have mediocre intelligence" are decidedly debatable, and statistics are not supplied to satisfy this broad view.

Developmental Anatomy: A Textbook and Laboratory Manual of Embryology. By Leslie Brainerd Arey, Ph.D., Sc.D., LL.D., Robert Laughlin Rea Professor of Anatomy, Northwestern University, Chicago. Fifth edition. Cloth. Price, $7. Pp. 616, with 590 illustrations. W. B. Saunders Company, W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury, London, W. C. 2, 1946.

This well known and much used textbook, while retaining its former fundamental structure, appears in a much improved form. The main divisions general embryology, special development and a laboratory manual of embryology have all been modified to some extent, and attractive new illustrations added, but it is the first part that has been the more widely modified with much rewriting, addition of materials and new illustrations. Noteworthy improvements include chapters on reproductive cycles and their hormonal control, embodying discussions of estrous cycles, menstrual cycles and their relations to one another as well as to other cyclic phenomena in the uterus, vagina and mammary glands. The hormonal control of these phenomena involves pituitary, ovarian and placental hormones as well as some brief discussion of testis hormones. Although of necessity somewhat brief, they include basic essentials and permit the student to glimpse these important aspects bearing on the process and biology of reproduction. The chapter on experimental embryology introduces the approach to the analysis of development by experiment and points out some of the methods of attack. Problems associated with the initiation of development, cleavage and gastrulation, early localization, potency, embryonic determination and induction present some of the dynamic aspects of development to enliven the more static phases of descriptive development. The treatment of gastrulation has conspicuously included more modern concepts, especially in the bird (although one outdated illustration is inadvertently retained in part 3). The inclusion of recent knowledge on early human development, placentation and a unification on embryonic membranes is commendable. Improvements are also noted on treatment of growth and of histogenesis. The new edition will be heartily welcomed

Penicillin: Its Properties, Uses and Preparations. Published by Direction of the Council of The Pharmaceutical Society of Great Britain. Cloth. Price, 10s. 6d. Pp. 199, with illustrations. Pharmaceutical Press, 17 Bloomsbury Square, London, W. C. 1, 1946.

This compact volume is the most recent of several monographs on penicillin. Its purpose is to present to pharmacists and general practitioners the methods of preparing and using penicillin. In the usual fashion there is an introductory summary of the history of this remarkable antibiotic, followed by chapters on the methods of manufacturing and the chemistry and properties of penicillin. Methods of assaying penicillin are detailed, and the pharmacology is described. These informative phases embrace over one third of the contents. Thirty-three pages are devoted to the clinical use of penicillin. Then forty-nine pages are given to a description of pharmaceutic preparations. The volume concludes with legal considerations relative to penicillin regulations in Great Britain and patent rights. Obviously detailed and pertinent information covering the many phases of infections is lacking for the general practitioner. Sir Alexander Fleming's monograph is more practical and valuable for the doctor. The volume has an excellent index and is documented with 331 key references to the overwhelming literature on penicillin.

An Atlas of the Commoner Skin Diseases. By Henry C. G. Semon, M.A., D.M., F.R.C.P., Physician for Diseases of the Skin, Royal Northern Hospital, London. Third edition. Cloth. Price, $12. Pp. 343, with 139 plates reproduced by direct colour photography from the living subject under the direction of Arnold Moritz, B.A., M.B., B.C. William Wood & Co., Mount Royal and Guilford Aves., Baltimore 2, 1946.

The author prefaces this book with the statement that it is not meant to take the place of the standard textbook but "as an atlas it is designed to illustrate and its chief function is to assist the visual memory." The book represents an admirable and ambitious project, and many of the illustrations are excellent pictures of the lesions as they occur on patients. Unfortunately, many more are only fair, and in several instances the illustrations are useless and ineffective because in the process of reproduction either overexposure or underexposure prevented accuracy. The value of the book might have been enhanced too had greater care been used in the selection of the material to be illustrated. The brief clinical descriptions that accompany the illustrations are excellent and are made more interesting in that they are in the form of condensed case reports with consideration given to differential diagnosis and treatment. The layout is also excellent, with the text arranged in accessible position to each plate in order to afford help in diagnosis and as an aid to memory. The book should be useful to the practitioner, but it will be of little help to the medical student because, despite the claim that "the color values are superior to any as yet produced by other processes," too many of the illustrations fail to serve their purpose as models for diagnosis and visual study.

Phases in the Drinking History of Alcoholics: Analysis of a Survey Conducted by the Grapevine, Official Organ of Alcoholics Anonymous. By *E. M. Jellinek, Sc.D., Director*, Section of Studies on Alcohol, Yale University. Memoirs of the Section of Studies on Alcohol, Laboratory of Applied Physiology, Yale University, No. 5. [Distributed by Quarterly Journal of Studies on Alcohol.] Paper. Price, $1. Pp. 88, with 4 illustrations. Hillhouse Press, 432 Temple St., New Haven, Connecticut, 1946.

This attempts through a questionnaire approach to survey within the admittedly limited scope of having been able to use only 98 completed questionnaires out of 1,600 circulated copies to members of lay alcoholic groups phases in the drinking history of alcoholic addicts with the resulting "main implications" contained in "most significant" and other "suggestions," which are presented as differing from, and do definitely differ from, present day medical psychologic thinking.

Water Supplies, Hepatitis, Associated Diseases and Fungi Infested Water in Assam. By Arnold John Teal, M.B., B.S., D.P.H., Medical and Sanitary Officer, The Mariani Medical Association, Assam. Paper. Price, Rs. 2 / 8 / —. Pp. 18. Doss & Co., Jorhat, Assam, 1945.

This is a conglomerate group of data, most of which do not lend themselves to scientific evaluation. Many of the recorded observations are of considerable interest but many must necessarily be considered as purely speculative and the conclusions drawn from them as empirical.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SUNBURN AND INTERMITTENT CLAUDICATION—BUERGER'S EXERCISES

To the Editor:—Is there any reason why an extremely severe sunburn of the lower part of the legs would cause intermittent claudication to develop? *Please outline the most satisfactory treatment for intermittent claudication.* Also kindly outline Buerger's exercises for this condition.

H. O. Pope, M.D., Niantic, Ill.

Answer.—To establish any connection between a severe sunburn and the development of intermittent claudication one would have to know the patient's general cardiovascular status, the time interval between the exposure and the development of symptoms and the extent of hemoconcentration as a result of the sunburn, as shown by an elevated red cell count or hemoglobin. Thermal burns may produce venous thrombosis and infrequently arterial thrombosis; this occurs in patients who show severe hemoconcentration. This factor, together with the action of broken down tissue products, does increase the clotting tendency. It is not likely, however, that a normal vascular tree would respond with occlusion to a sunburn and a vascular lesion; possibly a latent form must have been present before the burn.

Intermittent claudication is simply a symptom of vascular insufficiency on effort, and its treatment varies according to the cause of the vascular disease. When due to Buerger's disease, the active process must be brought to a quiescent stage before collateral circulation can be stimulated. If due to an embolus, the source of the blood clot must be looked for, which is usually in the heart. In peripheral vascular sclerosis, factors such as diabetes, hypertension and lipemia may be controlled to a certain extent. After the nature of the underlying disease is understood, treatment may be directed toward increasing blood flow to the affected extremity. This may be done with drug therapy, although none of the drugs used at present have any but temporary effect. Heat can be used, never to the affected limb, but to the root of the limb or the trunk in the form of heat cradles, electric pads or short wave diathermy. Sympathectomy in the properly selected case may increase walking ability and is a protective measure against gangrene.

Buerger's exercises, as modified by Allen, are carried out as follows: The patient lies on his back and elevates his legs to an angle of 30 to 45 degrees, resting it on a support until his feet blanch; this may take from one to three minutes. In the second position the patient sits with his legs hanging over the edge of the bed, and the feet and toes are put through a series of motions; this is continued until maximal rubor occurs. This hyperemia may take a few minutes to develop. In the third position the patient rests horizontally wrapped in a woolen blanket for five minutes. These cycles are repeated for a period of an hour and may be done several times daily. It is doubtful that such exercises are of much value; they act by an alternate filling and emptying of the venocapillary bed, which can be accomplished more effectively with much less effort and for longer periods of time by an automatically operated rhythmic constrictor. Both Buerger's exercises and the alternate hot and cold baths are being widely used without impressive evidence of their usefulness.

ROUTINE ANTEPARTUM Rh TESTS

To the Editor:—What are the advantages and disadvantages of Rh factor determinations in expectant parents? Should this be as routine as the serologic test for syphilis?

Herman Goodman, M.D., New York.

Answer.—Antepartum tests for the Rh factor may disclose the possibility of fetal erythroblastosis in the baby to be born by finding Rh antibodies in the Rh-negative wife of an Rh-positive man. Occasionally Rh antibodies may even be found in an Rh-positive woman whose Rh type differs from her husband's. Such finding will warn the obstetrician to be on his guard at the time of the child's birth. If any evidence of fetal erythroblastosis is found, especially anemia, immediate therapy with Rh-negative blood transfusion may be instituted without any loss of time. Experience has shown that the speed with which therapy is instituted is frequently a deciding factor in the success.

It is essential to know the Rh factor of any woman, especially if pregnant, in order to have available suitable blood in case a transfusion is needed.

There is no possible disadvantage in Rh testing. It is good to keep in mind that finding of an Rh-negative factor in the mother and an Rh-positive factor in the father does not mean that the child will necessarily be afflicted with the disease. Only in a relatively small number of such marriages are the children afflicted. Furthermore, the first child is almost always well, unless the mother had a transfusion of Rh-positive blood prior to pregnancy.

The present consensus is that Rh testing should be a routine antepartum test.

INFECTIOUS LYMPHOCYTOSIS AND LYMPHOCYTIC LEUKEMIA

To the Editor:—Please discuss the differential diagnosis between acute infectious lymphocytosis and chronic lymphocytic leukemia, with emphasis on hematologic differences and findings on physical examination.

Lieutenant, M. C., A. U. S.

Answer.—Acute infectious lymphocytosis is mainly a disease of children, although a few cases have been observed in young adults. The clinical symptoms are extremely mild and there is usually no adenopathy or splenomegaly. The white blood cell count rises rapidly sometimes to as high as 100,000, with a high percentage of mature lymphocytes. The red cells and platelets are unaffected. After a few weeks the white blood cell count begins to go down and the blood picture returns to normal within three to seven weeks.

Chronic lymphatic leukemia is practically unknown in children. There is a slow and progressive rise in the white cells, which are predominantly mature lymphocytes. Slight anemia and thrombopenia are common. The bone marrow shows a greater degree of lymphopoiesis than is present in infectious lymphocytosis. As the leukemia progresses, the lymph glands and spleen enlarge.

It is not possible to distinguish chronic lymphatic leukemia from infectious lymphocytosis by the examination of a single blood film. However, the clinical course readily differentiates these two conditions.

DERMATITIS AND FIVE CENT COIN

To the Editor:—A patient has a dermatitis around the hairline of both temples. The allegation has been advanced that this dermatitis is a dermatitis venenata due to a new substance or metal added to the five cent coin during the war. It is further rumored that the government *tried to recall all these coins because of this factor. Is this true?*

M.D., Michigan.

Answer.—The regular composition of the five cent coin before the war was 25 per cent nickel and 75 per cent of copper. During the war the composition was changed to 35 per cent silver, 9 per cent manganese and 56 per cent copper. Since Jan. 1, 1946 the composition has been the same as it was before the war, namely 25 per cent nickel and 75 per cent copper.

In answer to a direct inquiry, the Department of the Mint stated that there were no cases of dermatitis caused by the wartime nickel, nor were any nickels recalled.

In a case of dermatitis around the hairline of both temples, spectacle frames made either of alloys or of plastics are to be suspected. The most common metal in an alloy causing sensitization dermatitis is nickel. Any incompletely cured or polymerized plastic is capable of causing sensitization dermatitis.

VITAMIN K DOSAGES

To the Editor:—In Queries and Minor Notes (The Journal, Dec. 7, 1946, p. 893) there was a discussion of the dosage of vitamin K in the prevention of hemorrhagic disease in the newborn. A pertinent fact which was not mentioned prompts me to write that the various vitamin K preparations available on the market do not exhibit the same vitamin K activity. *To illustrate, 1 mg. of menadione, according to the definition of the* methyl-naphthoquinone (MeNQ) unit, is equivalent to 1,000 such units. *However, 1 mg. of Hykinone (menadione sodium bisulfite)* contains only 625 MeNQ units (Gutman: Modern Drug Encyclopedia, ed. 3, p 365) and an equal weight of Synkayvite (2-methyl-1, 4-naphthohydroquinone diphosphoricester tetrasodium salt) yields even less, namely 490 MeNQ units (Almquist, H. J.: *Physiol. Rev.* 21: 194 [Jan.] 1941). The Journal quotes 2 mg. of menadione as a dosage level. This is equivalent to 4.08 mg. of Synkayvite. The activity of the particular preparation being *used should be known. In converting vitamin K compounds* from insoluble to water soluble forms, the molecular weight is increased. All vitamin K compounds should be *compared with menadione on a molecular* and not on a weight basis, and for uniformity and simplicity it is suggested on the basis of biologic vitamin K units.

Shepard Shapiro, M.D., New York.

THE CLINICAL USE OF ANTICOAGULANTS

Report of Treatment with Dicumarol in 1,686 Postoperative Cases

Chairman's Address

EDGAR V. ALLEN, M.D.
Division of Medicine, Mayo Clinic
Rochester, Minn.

If blood did not possess the quality of coagulation, injuries would allow it to leak from the body as freely as water leaks through a sieve. This knowledge, which is possessed by every physician, has dominated medical thinking about coagulation of the blood. A vast proportion of the efforts of physicians interested in coagulation has been devoted to making blood clot better, because of observation of the consequences of blood which clots poorly. There are few physicians who have not wished for an efficient method by which they might stop [illegible] quite clear now that thoughts of the [illegible] must be directed in the reverse direction as well; in some circumstances there are great benefits if the property of coagulation of blood is impaired. When the vascular system of the blood is intact, coagulability of the blood may be reduced substantially without harm, and indeed with benefit. It is doubtless true that hemorrhage causes far fewer deaths than intravascular thrombosis. The problem of intravascular thrombosis is, therefore, more important than the problem of hemorrhage.

It may be well to remark parenthetically that nature provides in abundance, even in excess. Thus, although one of each of the organs named is adequate for normal life, there are two ovaries, two eyes, two testes, two kidneys and two suprarenal glands; although only one spermatozoon is necessary to fertilize an ovum, large numbers ordinarily make the attempt. Gastric secretions, bile and intestinal secretions are produced in superabundance. It is timely to consider that blood may normally clot too well to serve the best interests of the health of man. The protective device provided by nature is actually harmful as well as protective. Nature has provided not wisely but too well. This conception requires acceptance of two verities: man and animals may live normally (in the absence of injury) if coagulation of the blood is substantially impaired, and thrombosis of blood vessels occurs less readily when blood clots less well than normally.

The importance of diseases of blood vessels would be greatly lessened if vascular disease did not provoke thrombosis and if blood would not clot inside living blood vessels. Phlebitis would be a benign disease if it did not cause venous thrombosis. Arteriosclerosis would have lesser importance if it did not cause coronary and cerebral thrombosis. The two chronic occlusive arterial diseases of the extremities, arteriosclerosis obliterans and thrombo-angiitis obliterans, would not cause any great impairment of the arterial circulation to the extremities if thrombosis were not a part of them. The curse of cardiac irregularities, coronary thrombosis and congestive heart failure would be substantially smaller if mural thrombosis and embolism were not associated with them. There would be no pulmonary embolism or phlebothrombosis if blood would not clot inside blood vessels; the gangrene of trench foot and immersion foot would be avoided in many instances. These observations emphasize that the health of man would be greatly improved if intravascular thrombosis did not occur. That which is desired is a method of impairing coagulation so that intravascular coagulation will not occur while the protective mechanism of coagulation, which prevents bleeding, remains. The use of anticoagulants is a step in the direction of achieving the prevention of intravascular thrombosis.

Currently, there are two preparations clinical use of which impairs the coagulation of the blood: heparin and Dicumarol (3,3′-Methylene-bis-[4-hydroxycoumarin]). The advantages and disadvantages of the use of them are outlined in table 1.

Both anticoagulants have the disadvantage that hemorrhage may result from the use of them. Every physician who uses anticoagulants must steer a course between the Scylla of too little and the Charybdis of too much. Advantageous as both heparin and Dicumarol are, use of them represents only the first step in the direction of securing satisfactory anticoagulants for clinical use.

Viewed in the light of present day knowledge, the requisites for an entirely satisfactory anticoagulant for clinical use are: (1) lack of harmful side effects when used for short periods or for months or years; (2) a predictable effect on coagulation of a specified amount of the drug (possibly based on estimation of blood volume); (3) prompt control of its effect by a "counter" drug in order to prevent and control bleeding; (4) a method of calculating the effect on blood which is simple and rapid, which will give consistent results and which can be performed satisfactorily by relatively unskilled technicians or physicians; (5) effective oral administration, and (6) cheapness. The spread between ideal and practical may be great, and for the time being the members of the medical profession must be satisfied with less than that which is desired. Indeed, the two anticoagulants now available for clinical use have been administered with advantage, although neither is an ideal preparation.

Read in a Symposium on "Treatment" before the Section on Experimental Medicine and Therapeutics at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

There are many misconceptions about intravascular thrombosis. Fatal pulmonary embolism is thought to be almost solely the lot of the patient who has had a major surgical operation; yet as great a proportion of patients who are sick with "medical" conditions die from pulmonary embolism as of those who have had operations.[1] Even in lobar pneumonia, thromboembolism occurs in about 2 per cent of cases.[2] It is thought that venous thrombosis is relatively uncommon; yet studies show that about half of all middle-aged and older patients who have died after being in bed for varying periods had thrombosis of the deep veins of the legs.[1] Most physicians consider that most patients who died from pulmonary embolism died suddenly; yet evidence shows that about two thirds of them lived more than an hour, a period which permits treatment.[3] Experimental studies on animals have indicated the nature of this treatment. A report of recovery of 35 of 45 patients who had pulmonary embolism may indicate that this treatment is beneficial.[3] Aside from the clinical syndrome of classic thrombophlebitis, many physicians have believed that venous thrombosis cannot be recognized ordinarily. There is increasing evidence that bland venous thrombosis produces signs and symptoms which may be recognized easily by the experienced physician.[3] Until recently intravascular thrombosis and its consequences have been considered largely inevitable. Pulmonary embolism has, for example, been considered a catastrophe which was unavoidable. These and other observations emphasize the need for wide dissemination of current knowledge of thrombosis and embolism of blood vessels.

Table 1.—*Comparison of Anticoagulants*

- I. Heparin
  - *A.* Advantages
    - 1. Quick effect on the blood
    - 2. Quick disappearance of the effect on the blood
    - 3. Can be administered without laboratory control
  - *B.* Disadvantages
    - 1. Expensive *
    - 2. Need for parenteral administration
- II. Dicumarol
  - *A.* Advantages
    - 1. Inexpensive *
    - 2. Effective orally
  - *B.* Disadvantages
    - 1. Effect on the blood is delayed
    - 2. Effect on the blood persists for days after the cessation of administration
    - 3. Daily determination of prothrombin time necessary for efficient and safe administration

* Heparin injected intravenously in amounts of 50 mg. every four hours currently costs about $9 a day. Enough Dicumarol to produce the desired effect on the blood costs only a few cents each day.

THE HISTORY OF HEPARIN AND DICUMAROL

In 1918 Howell and Holt[4] devised the word "heparin" to indicate the hepatic origin of a heparphosphatide described by MacLean in 1916. Since that time there have been numerous reports on the chemistry of heparin, its effect on blood both in vivo and in vitro and its use under experimental conditions and in clinical practice. The most recent of the clinical reports is that of Bauer,[5] who reported its use in 209 cases of acute thrombosis of the veins of the legs.

I have reviewed the history of Dicumarol in a previous publication.[6] In brief, Dicumarol is the substance which Link and his collaborators determined to be the cause of spoiled sweet clover disease of animals, a hemorrhagic disease leading to the death of many animals which ate spoiled sweet clover. Its identification, the determination of its chemical formula, its synthesis and other studies mark an epoch in research which is admirably presented in the Harvey lecture for 1943-1944.[7] My associates and I secured some of the material from Link in 1941, and the first report on its clinical use was published in June 1941.[8] However, Meyer and his associates at Wisconsin General Hospital had administered Dicumarol to man before we first gave it to a patient in May 1941. Since that time my associates and I have published a number of clinical reports.[9] Other students of the drug have made substantial contributions.[10] One of the most extensive of these is the report of Bruzelius, who administered Dicumarol to 1,658 patients. Prophylactic use in 1,448 postoperative cases caused a two-thirds reduction in the incidence of venous thrombosis and pulmonary embolism; there were but 19 cases of thromboembolism in the treated group. Treatment of 113 patients with thromboembolism caused a reduction of three fourths in the incidence of subsequent thromboembolism and a decrease in duration of fever and in the number of days of confinement of patients to bed. Later in this presentation I shall discuss experiences with Dicumarol in the treatment of 1,686 patients who have been operated on. This has been a cooperative study which has been participated in by internists and surgeons, chief among whom are Drs. N. W. Barker, E. A. Hines Jr., Walter F. Kvale and John M. Waugh, with the technical assistance of Miss Margaret Hurn. The story of the evolution of the clinical use of this anticoagulant Dicumarol has been aptly described by a newspaper reporter under the heading "From the haystack to the human."

THE ACTION OF HEPARIN AND DICUMAROL

The mode of action by which heparin interferes with coagulation of the blood has not been definitely determined. The product of heparin and heparin complement may be antiprothrombin or it may serve to activate a precursor to antithrombin. It appears to inhibit the conversion of prothrombin to thrombin and to prevent the clotting of fibrinogen by thrombin.[11] There is considerable evidence that heparin is the normal circulating anticoagulant, assisting in, or necessary to, the maintenance of the fluid state of the blood in man.

Dicumarol affects the blood by depressing the values for prothrombin. There is indirect evidence that it accomplishes this by suppressing the formation of prothrombin, but the exact mechanism of its action is unknown.

THE SIMULTANEOUS USE OF HEPARIN AND DICUMAROL

Because the effect of Dicumarol is delayed after oral administration, heparin must be used when an effect on coagulation of the blood is desired quickly. Heparin is effective within a few minutes, but Dicumarol may not be effective for twenty-four to forty-eight hours or longer. The usual program when an effect is needed quickly in the treatment of adults with anticoagulants is to inject 50 mg.[12] of undiluted solution of heparin intravenously and to administer 300 mg. of Dicumarol by mouth. Treatment with the latter is continued as indicated in the following paragraph, and heparin in amounts of 50 mg. is injected intravenously every four hours, until studies of the prothrombin indicate reduction to a satisfactory value (about 20 per cent). Although in theory heparin should be administered by continuous intravenous injection, the intermittent injection of it produces satisfactory results in clinical use. During treatment with heparin, blood should be drawn for determination of the value for prothrombin at least three hours after the last intravenous injection of heparin to avoid the effect of heparin itself on the prothrombin time.

THE DOSAGE OF DICUMAROL

It cannot be too strongly emphasized that the administration of Dicumarol must be based on the value for prothrombin in the blood. Any other program may lead to disaster from hemorrhage or to inadequate control of coagulation. Identical amounts may produce widely dissimilar effects on prothrombin when administered to different persons. Indeed, the prothrombin of the blood of the same person may be affected dissimilarly by the same amount of Dicumarol given on one or more than one occasion. The *sine qua non* of treatment with this preparation is an experienced and absolutely reliable laboratory service. At the Mayo Clinic the Magath modification of the Quick method of calculating the value of prothrombin has been found to be entirely reliable.[13] With this method normal values for prothrombin give a prothrombin time of 19 to 21 seconds. A prothrombin time of 27 seconds indicates 30 per cent prothrombin, 35 seconds indicates 20 per cent prothrombin and 60 seconds indicates 10 per cent prothrombin in the blood. I make a plea for discontinuation of reporting prothrombin time. Since thromboplastins vary in potency, the time reported by a group of investigators cannot be interpreted by other investigators using another thromboplastin. In the interest of uniformity every laboratory should report the prothrombin not in seconds but in percentage of normal. At the very least, every publication should contain the prothrombin time for three critical values of prothrombin, 30 per cent, 20 per cent and 10 per cent.

Attention must be given to the thromboplastic substances used, for they vary in potency. Identical prothrombin times for two lots of thromboplastin may indicate entirely different values for prothrombin (percentage of normal). When the Quick test for prothrombin time is performed repeatedly during treatment with Dicumarol, either each batch of thromboplastin must be proved to have the same potency as the former or a new dilution curve should be plotted for each new batch. The problem has been simplified by the observation that the critical figures in treatment with Dicumarol are those representing 10 per cent, 20 per cent and 30 per cent of normal prothrombin. One may administer the drug adequately knowing only these figures, for clinical experience has indicated that intravascular thrombosis rarely occurs when the percentage prothrombin in the blood is less than 30, and bleeding rarely occurs when the percentage prothrombin is 10 or more.

Three hundred milligrams of Dicumarol is given on the first day, and 200 mg. is given on the second day. On each subsequent day of therapy the percentage prothrombin is determined and reported. If the value is more than 20 per cent, 200 mg. of the drug is given; if it is less than 20 per cent none is given. There are minor exceptions to this program. If the patient's blood is sensitive to the effect of Dicumarol, only 100 mg. may be given instead of 200 mg. If the patient's blood is insensitive to the effect of the drug, 300 mg. may be given instead of 200 mg. If the percentage prothrombin is decreasing rapidly but is more than 20, no Dicumarol is given. If it is rising rapidly but has not yet reached 20 per cent, the drug is given on that day. Ordinarily the postoperative treatment of patients with Dicumarol is begun on the second or third postoperative day, when used prophylactically, or when signs of venous thrombosis or embolism occur. Its administration is continued until the patient has been ambulatory for three to seven days. The effect of Dicumarol ordinarily continues for a few days after the discontinuation of treatment. In many of these cases heparin is used for a short time at first.

CONTROL OF EXCESSIVE PROTHROMBIN DEFICIENCY AND INDUCED HEMORRHAGE

It was originally believed that vitamin K was ineffective in correcting prothrombin deficiency induced by Dicumarol. It is now known that the amounts of vitamin K which were used were entirely inadequate.[14] It is of some historical interest that Butt and I gave 30 mg. of synthetic vitamin K intravenously to the first patient to whom we gave Dicumarol. There was a prompt increase in the value for prothrombin in the blood. We misinterpreted this as a natural event, not due to the intravenous injection of vitamin K. We did not recognize our error until a considerable time after others had shown that large amounts of vitamin K would correct the hypoprothrombinemia induced by Dicumarol. Cromer and Barker[15] showed that 64 mg. of menadione bisulfite, injected intravenously, corrected excessive prothrombin deficiencies in 35 of 37 cases, and bleeding ceased. Transfusion of 500 cc. of fresh blood is also effective; blood may need to be given until bleeding stops and the anemia is corrected.

[12] Bauer[5] reported use of 100 to 150 mg. injected intravenously at intervals not smaller than every four hours. I doubt that such large amounts are necessary.

[13] Magath, T. B.: Technic of Prothrombin Time Determination, Am. J. Clin. Path. (Tech. Supp.) **3**: 187-189 (Sept.) 1939.

The appearance of excessive prothrombin deficiency (less than 10 per cent) is a signal to discontinue Dicumarol therapy temporarily and to resume with smaller doses. If an emergency operation must be performed on a patient who is receiving heparin, discontinuation for two hours or so will permit the blood to return to a normal state of coagulability. If an emergency operation must be performed on a patient receiving Dicumarol, transfusions and large amounts of vitamin K may be given to return the percentage of prothrombin toward normal values.

INDICATIONS FOR ANTICOAGULANT THERAPY

The indications for anticoagulant therapy are as follows: (1) after nonfatal pulmonary embolism to prevent further embolism which may be fatal; (2) for thrombophlebitis and phlebothrombosis, to prevent further venous thrombosis and pulmonary embolism and to lessen the possibilities of resultant chronic venous insufficiency (edema, varices, ulcers and indurative cellulitis); (3) for sudden arterial occlusion (embolism and thrombosis) to prevent arterial thrombosis which results from ischemia of the intima (distal to the area of occlusion) and to prevent thrombosis of an artery at the site of embolectomy, if a surgeon removes the embolus;[16] (4) to avoid thrombosis in cases of traumatic injury to blood vessels; (5) as prophylaxis against postoperative venous thrombosis in cases of previous thrombosis or embolism, because of the increased probability of further venous thrombosis or embolism, and (6) after abdominal hysterectomy because 4 per cent of patients who undergo this operation have postoperative venous thrombosis or embolism and 0.7 per cent die of fatal embolism.[17] Anticoagulant therapy may be used prophylactically after other operations.

POSSIBLE INDICATIONS FOR USE OF ANTICOAGULANTS

The possible value of the use of anticoagulants in acute myocardial infarction, congestive heart failure and irregularities of the heart beat, particularly auricular fibrillation, is being studied by a number of investigators. The recent reports of reduction of the mortality rate in acute myocardial infarction and of embolic phenomena are most exciting.[18] Further studies are necessary before there can be a final opinion. The usefulness of anticoagulant therapy in the chronic occlusive arterial diseases has not been satisfactorily evaluated. Anticoagulants seem to have no value in the treatment of subacute bacterial endocarditis.

CONDITIONS IN WHICH ANTICOAGULANTS ARE TO BE USED CAUTIOUSLY OR NOT AT ALL

In the following conditions anticoagulants are to be used cautiously or not at all: (1) ascorbic acid and vitamin K deficiencies or hepatic disease, because anticoagulants probably are not needed and use of them may magnify the tendency to bleed, with disastrous results; (2) renal insufficiency, because the effect of Dicumarol is greatly enhanced and prolonged; (3) blood dyscrasias with impairment of normal mechanism for the prevention of bleeding, because anticoagulants magnify the tendency to bleed; (4) recent surgical operations on the brain or spinal cord, because even a small amount of bleeding in these regions may be disastrous, and (5) ulcerative lesions or open wounds, because of magnification of the tendency to bleed.

THE DANGER OF BLEEDING AS A RESULT OF THE USE OF ANTICOAGULANTS

The sole danger from the judicious use of anticoagulants is hemorrhage. That this danger is minimal when heparin is used is supported by my own observations and well substantiated by the report of Bauer,[5] who stated: "Puerperal bleeding was not influenced, and existing traumatic hematomas were not enlarged. We were not afraid of heparinizing even patients bleeding from gastric ulcers; nevertheless, some caution should probably be exercised in cases of that kind." Murray and Best[19] reported that heparin may be administered one to three hours after operation with little danger from hemorrhage if thorough hemostasis is practiced. It is well to emphasize that if anticoagulants are to be used, heparin should be used in preference to Dicumarol whenever the physician is not well informed about the use of the latter or when reliable laboratory facilities are not available.

Inasmuch as its effect on the coagulation of the blood disappears about two to three hours after discontinuation of the injection of heparin, there is usually no need to attempt to reduce the artificially induced prolongation of the coagulation time which results from the intravenous injection of this preparation. Two of my associates, Drs. Parkero and Koole, have had considerable experience with protamine, which has been found to counteract promptly the effect of heparin.

It is deplorable that serious and fatal bleeding has been reported to follow the uncontrolled use of Dicumarol. This production of hemorrhagic sweet clover disease of animals in man is a reflection not on Dicumarol but on the method of its use. It is not enough that the drug be used; it must be used expertly and only when determination of the prothrombin time, at daily intervals, is wholly reliable. Our own experiences in the use of Dicumarol in 1,686 postoperative cases have indicated that minor hemorrhage (epistaxis, hematuria, petechiae and ecchymoses) occurs in 3.1 per cent. When these complications occur in minor degree, vitamin K in amounts of 30 to 60 mg. is injected intravenously, provided studies of prothrombin indicate that the values for prothrombin are approximately 10 per cent or less. In these instances it is not desired to return the prothrombin value to normal but only to return it to values somewhat less than 30 per cent. Treatment with Dicumarol may be resumed cautiously. If the complications are serious, and this is seldom true, it may be necessary to give enough vitamin K to return the values for prothrombin to normal. If desired, treatment with Dicumarol may be resumed cautiously when bleeding has ceased. In our series of 1,686 postoperative cases major bleeding (usually from operative wounds) occurred in 1.9 per cent of the patients treated. Two patients of this entire group died as a result of hemorrhage.

REPORT OF CASES

Case 1.—Resection of the duodenum of a woman aged 41 was performed because of carcinoma of the duodenum. Dicumarol was administered over a period of fifteen postoperative days. The highest prothrombin time was 36 seconds, representing about 20 per cent of normal prothrombin. On the day before fatal hemorrhage into the gastrointestinal tract and from the stab wound in the abdomen, the prothrombin time was 28 seconds, representing about 30 per cent of normal prothrombin. Necropsy was not performed. Examination of the specimen removed at operation showed carcinomatous involvement of the peritoneum and lymph nodes.

Fatal hemorrhage occurred in spite of adequate control of administration of Dicumarol. Unfortunately, necropsy was not performed; the source of the bleeding was not determined; bleeding may have been unrelated to treatment with the drug. This experience emphasized the need for caution in administering Dicumarol to patients who have had surgical operations on the gastrointestinal tract.

Case 2.—A man aged 46 was operated on in February 1946 for excision of an area of gastrojejunitis with jejunal ulcer and gastrocolic fistula. A gastroduodenostomy was performed (von Haberer-Finney modification), and the opening in the colon was closed. The patient was dismissed from the hospital on the fifteenth postoperative day, but that same day he noted soreness in the left calf. Three days later he was readmitted to the hospital for venous thrombosis of the left calf; ulcer-like symptoms were observed. Treatment with Dicumarol was begun. Two days later the prothrombin time was 58 seconds, and the following day it was 72 seconds. Synthetic vitamin K was given. The following day the prothrombin time was 29 seconds. One day later there was evidence of hemorrhage into the gastrointestinal tract. Synthetic vitamin K and transfusion of blood were given. A diagnosis of recurrent hemorrhagic duodenal ulcer was made. The prothrombin times for successive days were 44, 32, 28, 24, 23, 21 and 23 seconds. Bleeding into the gastrointestinal tract continued in spite of repeated transfusions of blood and injections of vitamin K and the maintenance of essentially normal prothrombin times. Death from hemorrhage occurred on the tenth day of bleeding. At necropsy a recent duodenal ulcer was found, which had eroded an artery; there was evidence of hemorrhage into the duodenum.

It seems improbable that Dicumarol was responsible for the fatal outcome in this case. The bleeding was caused by a new ulcer in the duodenum, which had eroded into an artery in the duodenum. Bleeding had continued in spite of the administration of large amounts of vitamin K and large and repeated transfusions of blood, which had corrected essentially the prothrombin deficiency. Nonetheless this experience emphasized the need for caution in the administration of Dicumarol to patients who have gastrointestinal lesions.

It has been our custom to inject 30 to 60 mg. of a preparation of synthetic vitamin K intravenously and to transfuse the patient if serious bleeding occurs; the injection of vitamin K may be repeated at four to six hour intervals, two to three times as necessary. If bleeding is minimal, vitamin K only is given. When bleeding stops, treatment with Dicumarol may be resumed cautiously if the need for anticoagulants still exists.

THE EVIDENCE THAT HEPARIN AND DICUMAROL PREVENT INTRAVASCULAR THROMBOSIS

Murray and Janes [20] have shown that when heparin was not used glass tubes bridging the gaps in arteries of dogs became plugged in twenty minutes on the average. When heparin was used these cannulas remained patent for periods up to seventy-six hours in most cases. Murray and Best [19] concluded that "experimentally, heparin will prevent thromboses in blood vessels." Murray used heparin after operations on 444 patients. Postoperative pulmonary embolism did not occur. Twenty-nine patients who had pulmonary embolism were treated; all survived.[21] Similar results were reported by McClure and Lam.[22] Crafoord and Jorpes [23] treated 325 patients postoperatively with heparin. Thromboembolic phenomena did not occur, although such complications occurred in 9 per cent of a control series of 1,111 similar cases. Bauer reported a study of 209 cases of acute thrombosis of deep veins of the leg in which heparin was used in treatment. The mortality rate was reduced to a tenth, the length of stay in bed was reduced from about forty days to less than five days and the incapacitating after-effects apparently did not occur in the majority of cases.[5] These studies emphasize that interference with the normal mechanism of coagulation of the blood by the administration of heparin will prevent or decidedly inhibit intravascular thrombosis of blood.

Studies on the thrombus-producing effect of monoethanolamine when injected into veins have indicated that the use of Dicumarol reduces the incidence of such

thrombosis from 50 per cent to 6.6 per cent.[24] Bollman and Preston[25] showed that the tendency toward thrombosis in glass or metal cannulas interposed in arteries was greatly reduced when animals were given Dicumarol. Dale and Jaques[26] found that the administration of Dicumarol inhibited thrombosis in extracorporeal glass chambers connected with segments of the veins of dogs. Richards and Cortell[27] found that venous thrombosis produced experimentally by intravenous injection of a sclerosing soap solution was inhibited by the administration of Dicumarol.

There are a number of reports on prevention of venous thrombosis or prevention of extension of existing venous thrombosis of man as a result of treatment with Dicumarol.[28] The number of cases of my associates and me has increased gradually, and more recent experience supports the conclusion presented in earlier reports.[29] These indicate that administration of Dicumarol to man will prevent venous thrombosis or will limit its extension and prevent pulmonary embolism in most cases.

RESULTS OF CLINICAL STUDIES WITH DICUMAROL AT THE MAYO CLINIC

My associates and I have used Dicumarol in 1,686 surgical cases. The results are summarized in tables 2 to 4.

Table 2.—*Two Hundred and Eighty Cases of Postoperative Thrombophlebitis*

	Cases	
	Expected if Anticoagulants Were Not Used *	Occurred
Subsequent venous thrombosis or pulmonary embolism	68	8†
Fatal pulmonary embolism	16	0

* In this table and in tables 3 and 4 the expected cases are calculated on the basis of the rates given in the reports of Barker, Nygaard, Walters and Priestley.[17]

† One case of minor pulmonary infarction and 7 cases of thrombophlebitis; in 3 cases the percentage of prothrombin in the blood was more than 30.

In addition to the cases summarized in tables 2 to 4, 114 patients were treated with Dicumarol after surgical intervention because they had had venous thrombosis or pulmonary embolism previously. In 284 more operative cases the drug was used prophylactically. In no case did venous thrombosis or pulmonary embolism result. We have no figures to indicate the expected incidence of these events before the anticoagulants were used.

Our own studies indicate that treatment with Dicumarol is effective in preventing venous thrombosis or in preventing its extension once it has occurred. According to previous studies and this one, the lives of 73 patients have been saved by the prevention of fatal pulmonary embolism. Two hundred and eleven patients were spared from venous thrombosis and pulmonary embolism. No complete accuracy is claimed for these figures, inasmuch as they are derived from study of two groups of patients, with all the inaccuracies inherent in this method of contrasting results. Nonetheless, the results are striking and indicative of a beneficial effect.

Table 3.—*Seven Hundred and Sixteen Cases of Abdominal Hysterectomy*

	Cases	
	Expected if Anticoagulants Were Not Used	Occurred
Venous thrombosis or pulmonary embolism	29	2*
Fatal pulmonary embolism	5	0

* Both minor thrombophlebitis only.

This report does not indicate that Dicumarol is wholly and entirely effective in preventing venous thrombosis or the extension of already existing venous thrombosis. A perfect record would be almost too good to believe. It is recognized that venous thrombosis represents the summation of contrary effects of two processes: the stimulus to intravascular thrombosis and the thrombosis-deterring effect of an anticoagulant. When the stimulus to intravascular thrombosis is great, the countereffect of Dicumarol may not be sufficiently great to prevent intravascular thrombosis. Indeed, it has been noted that superficial phlebitis may occasionally provoke venous thrombosis in the presence of a satisfactory effect of Dicumarol. A similar experience has been noted in studies on animals.[24]

Some physicians have objected to the use of Dicumarol on the basis that it may not profoundly alter the coagulation time and should not therefore prevent intravascular coagulation. It must be remembered that studies of extravascular coagulation do not simulate the process of intravascular coagulation. Indeed, the various methods for determining extravascular coagulation time give widely divergent results, not because the property of coagulation of blood has been inherently modified but because the intravascular environment differs from that in the glass tubes used to determine coagulation time. Also it is well to remember that coagulation time, per se, may be a crude method for measuring the tendency of blood to clot. It seems apparent to me that the experimental and clinical studies show beyond the shadow of doubt that heparin and Dicumarol are effective in the prevention of intravascular thrombosis.

Table 4.—*Two Hundred and Ninety-Two Cases of Pulmonary Embolism in Which Anticoagulant Therapy Was Used*

	Cases	
	Expected if Anticoagulants Were Not Used	Occurred
Subsequent venous thrombosis or pulmonary embolism	127	3
Fatal pulmonary embolism	53	1*

* Occurred after prothrombin time had returned to normal.

ANTICOAGULANTS VERSUS LIGATION OF VEINS

When venous thrombosis has occurred treatment is required for two purposes: to prevent further thrombosis and to prevent pulmonary embolism. There are two currently competitive programs of treatment: ligation of veins and the use of the anticoagulants, heparin and Dicumarol. Neither program of treatment is generally considered superior to the other, although each has its proponents who see a little virtue in the other. The proponents of venous ligation believe that this simple method of interrupting the continuity of a vein prevents the transportation of a clot by the blood. That is true for the single vein which is ligated. Those who see less virtue in the ligation of veins believe that thrombi may originate in other veins and thus cause pulmonary embolism; indeed the figures on venous ligation indicate that this is true. There is a report of ligation of peripheral veins in 39 cases. After ligation pulmonary embolism occurred in 9 cases and 3 patients died of pulmonary embolism. In 5 of the 9 cases, the emboli in a pulmonary artery originated from the leg opposite the one in which the vein was ligated.[30] An earlier report indicated that 11 cases of pulmonary embolism followed ligation of femoral veins of 202 patients.[31] Nevertheless this operative procedure has definite value: However, ligation of veins does not stop venous thrombosis; it simply prevents pulmonary embolism from originating in the distal part of the ligated vein. Ligation of the inferior vena cava is admittedly an effective measure, but the question relative to the advisability and necessity of such a "major" procedure has not been satisfactorily answered. Disaster may even follow ligation of a femoral vein for venous thrombosis.[32] Evans [33] has reviewed objections to the ligation of veins.

[28] Footnotes 8, 9 and 10.

[29] Footnotes 8 and 9.

My associates and I have had little experience with ligation of veins for the prevention of pulmonary embolism. My experience does not permit evaluation of this procedure. However, a study of published reports indicates that the judicious and expert use of anticoagulants is at least as effective in preventing pulmonary embolism as is ligation of veins Moreover, the use of anticoagulants usually prevents further venous thrombosis throughout the body, while ligation of veins is aimed chiefly at preventing pulmonary embolism.

It is my current opinion that the expert use of anticoagulants produces results which are better than those which follow ligation of veins. There is one exception to this statement. When venous thrombosis and pulmonary embolism occur repeatedly over a considerable period, weeks or months for example, ligation of a vein may be superior to anticoagulant therapy because of the difficulty of administering anticoagulants over a long period.

It is not the purpose of this presentation to assess finally the respective merits of ligation of veins and anticoagulants; that can be accomplished only after further experience. The use of both measures has brought interest in venous thrombosis to a place of desirable prominence. It is safe to predict that medicine stands on the threshold of new and satisfying experiences in this field. Sometime in the future there may be no valid reason why the coagulability of the blood in man may not be maintained indefinitely and safely at a level which will not permit intravascular thrombosis. Then medicine may look backward with pleasure instead of forward with anticipation.

CONCLUSIONS

1. Students of coagulation of the blood must give more attention to the desirability of impairing the ability of blood to clot within blood vessels. This statement is emphasized by the observation that hemorrhage causes many fewer deaths than intravascular coagulation of the blood.

2. Experimental and clinical studies indicate that coagulation of blood may be impaired by anticoagulants with the result that intravascular thrombosis usually can be prevented; hemorrhage occurs infrequently when anticoagulants are used expertly.

3. Heparin and Dicumarol (3,3′-methylene-bis-[4-hydroxycoumarin]) are fairly satisfactory anticoagulants, but they have deficiencies which make desirable a continued search for an ideal anticoagulant for clinical use.

4. Hemorrhage is the sole danger from the expert administration of these drugs. Minor hemorrhage occurred in 3.1 per cent and major hemorrhage in 1.9 per cent of 1,686 postoperative cases. Two deaths occurred from hemorrhage, but in 1 case bleeding was obviously not caused by Dicumarol, and there was doubt that the drug was responsible for bleeding in the other case.

5. In 280 cases of postoperative venous thrombosis there were but 8 cases of subsequent venous thrombosis (68 cases would have been expected without Dicumarol therapy) and no cases of fatal embolism (16 cases would have been expected without such treatment).

6. In 716 cases of abdominal hysterectomy there were but 2 cases of venous thrombosis (29 cases would have been expected without the use of Dicumarol) and no cases of fatal pulmonary embolism (5 would have been expected without the use of this drug).

7. In 292 cases of postoperative pulmonary embolism 3 cases of subsequent venous thrombosis occurred (127 cases would have been expected without Dicumarol therapy). Fatal pulmonary embolism occurred once (53 cases of fatal pulmonary embolism would have been expected without the administration of this anticoagulant).

8. The overall experience in this group of 1,686 cases indicates that approximately 73 lives were saved by the use of Dicumarol and that 211 patients were spared the experience of venous thrombosis and pulmonary embolism.

9. The respective virtues of venous ligation and anticoagulant therapy have not been determined in a manner which is wholly satisfactory. With one minor exception it appears that the expert use of anticoagulants produces results which exceed those which follow ligation of veins.

10. Medicine is on the threshold of new and satisfying experiences with methods for the prevention and treatment of intravascular thrombosis.

SPONTANEOUS REGENERATION OF SEVERED NERVES

LEWIS J. POLLOCK, M.D.

FRANK MAYFIELD, M.D.
ALEX J. ARIEFF, M.D.
ERICH LIEBERT, M.D.
Chicago
and
CAPTAIN Y. T. OESTER
Medical Corps, Army of the United States

It has long been known by physiologists and anatomists that it is more difficult to prevent regeneration of a severed nerve or one from which a large segment may have been removed than to obtain regeneration of the severed nerve after suture. This has been found to be true whatever measures may have been taken to prevent regeneration.

This is also well known to physicians who have attempted to prevent regeneration of the trifacial nerve when, after section of its peripheral branches, the proximal end may have been injected with alcohol or the nerve avulsed from its bony canal and the canal filled with bone plugs.

The failure to prevent regeneration of the distal segment of a severed nerve led some authors to attempt to refute the wallerian doctrine. Among the first were Philipeaux and Vulpian.[1] They performed experiments on young mammals, dogs, guinea pigs and chicks. They excised large portions of the sciatic, median, hypoglossal and other nerves. Months later on exposure of the distal segment of the nerve they found evidence of regeneration, although grossly the ends of the nerve seemed separated. When such a distal segment was stimulated by electrical currents, motor reactions of the muscles supplied by it were observed. On histologic examination numerous newly formed myelinated fibers were found. Finally, when this distal stump was itself resected, it again degenerated. They supposed that the fibers of the peripheral ends of severed nerves in young animals are able to regenerate without connection with their cells of origin. This strange method of regeneration they called "autogenous regeneration."

A number of other investigators repeated these experiments and, having come to the same conclusion, constituted a school of polygenists. Bethe[2] was a particularly strong advocate of this theory. He attempted to prevent regeneration of severed nerves by many devices and found that after "autoregeneration" the muscles of an extremity would contract when the peripheral segment of the nerve was stimulated by electrical currents but not when the proximal segment was so stimulated.

This characteristic was frequently observed during World War I and led a number of observers to espouse the theory of "autoregeneration." Perthes[3] in particular held this characteristic as proof of autoregeneration. Although Foerster[4] stated that he had repeatedly observed that a totally separated peripheral segment of a nerve could promptly be stimulated by electrical current despite the fact that the injury may have occurred as long as one or two years before, Platt[5] observed this in only 6 cases.

Although many others have found evidence of regeneration of the distal segment of an injured nerve when the ends seem to be separated by a gap, the theory of autoregeneration has been amply refuted by anatomists and physiologists. Among these may be mentioned Langley and Anderson, Halliburton, Howell, Huber, Lugaro, Ranson and many others. Ranson[6] has pointed out that nothing short of the complete removal of the entire lumbosacral spinal cord with the associated spinal ganglions can be regarded as effectively preventing actual regeneration from the proximal segment.

Cajal[7] well expressed the generally accepted opinion when he said: "Today no one can doubt that the newly-formed axons in a peripheral stump that has been violently separated from the central stump, cut over great distances, hidden in collodion tubes or folded back between muscles, really proceed from the proximal stump although the difficulties put in their way retard for a few months the arrival of fibers."

The question as to whether in every instance in which there is regeneration in the distal segment the fibers have found their way from the proximal segment or whether in some instances fibers may have broken through from adjacent uninjured nerves cannot be answered.

In some cases, as in 1 described by Perthes, in which the biceps and triceps muscles became innervated through outgrowths from the ulnar and median nerves, respectively, this may be a possibility.

In this study we propose to show that, far from being the exception, regeneration of a distal segment of an injured nerve, the segments of which are separated by gaps, is almost the rule provided a sufficient length of time has elapsed after injury. Proof that regeneration of the distal segment has occurred may be adduced by the recovery of voluntary motion exclusive of supplementary movement, recovery of sensation in the isolated supply of a nerve, histologic evidence of fibers in the distal segment, response of muscles to direct electrical stimulation of the nerve and such characteristics of response of muscle to electrical stimuli as exclude the state of complete denervation. These are: a chronaxia of less than 15 milliseconds or response of the muscle to faradic stimulation and, particularly, a galvanic tetanus ratio of more than 1.0. We[8] have previously shown that when some time after section of a nerve the muscles which it supplies are completely denervated and from the functional point of view consist of muscle alone the galvanic tetanus ratio is 1.0. As may be remembered, the galvanic tetanus ratio is the ratio between the threshold in milliamperes for the liminal response to galvanic stimulus of infinite duration and the threshold for sustained tetanus throughout the duration of the flow of a con-

stant current. In instances in which we were successful in preventing neural regeneration the galvanic tetanus ratio remained 1.0 for as long as a year; hence, it is our opinion that a muscle whose galvanic tetanus ratio is above 1.0 is not completely denervated. If one assumes that a galvanic tetanus ratio above 1.0 is indicative of some regeneration, then it should follow that in such a case when the ends of the segments of nerves separated by a gap are resected and sutured, the muscle should after a suitable time denervate and the galvanic tetanus ratio become 1.0. Inasmuch as regeneration and degeneration proceed simultaneously, there are instances in which the galvanic tetanus ratio may never be found to be 1.0. In this study we shall nevertheless restrict ourselves to cases in which the galvanic tetanus ratio became 1.0 after suture although it was above 1.0—often as high as 5.0—before suture. When, because of evidence previously described, it was considered that neurotization of the distal segment had occurred despite the presence of a gap, we were able in many instances to confirm this opinion by histologic study.

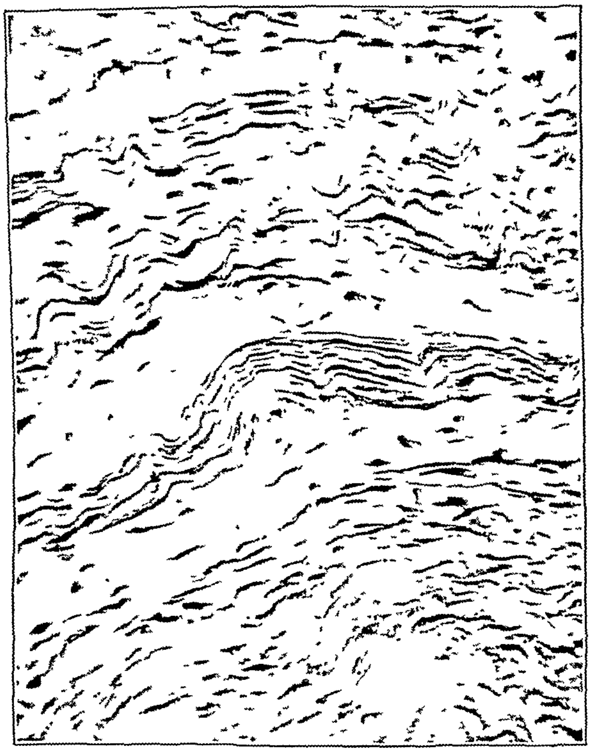

Fig. 1.—Radial nerve showing small neurofibrils along the periphery of the Schwann sheath cells

In most previous investigations myelin sheath stains and the Bielschowsky method were used to identify nerve structures in the peripheral segment. In our series the Bodian-Silver impregnation method was chosen for the study of neurofibrils because of the uniform results obtained with this method and because uniform sections may be cut from the paraffin-embedded material. The Bodian preparations were counterstained with Van Gieson fuchsin, which allows a good differentiation between the red-stained connective tissue and the darkly stained fibrillary structures.

In the majority of cases thin, fine, fibrillary structures could be seen lying closely adjacent to the Schwann sheath cells. They were darkly stained, and, in spite of their close relationship to the elongated, often swollen and sometimes vacuolated Schwann cells, these structures could easily be identified as being separated from the cellular structures. Because of their position and their staining qualities it seemed reasonable to assume that these fibrillary structures were newly-formed neurofibrils. They were finer and thinner than those found in the proximal stump and they usually had a rather irregular course, so that often only small segments of these fibrils could be seen without moving the focus of the microscope.

EVIDENCE FOR SPONTANEOUS REGENERATION

Among the cases selected for a study of the kinetics of stimulus at the Percy Jones General Hospital were 84 instances in which at operative intervention the ends of severed nerves were separated by gaps up to 9 cm. in length. Only in 1 case, that of an injury to the median nerve, was stimulation of the distal segment effective in producing motion in some of the muscles supplied by the nerve.

In 12 cases the chronaxia was less than 15 milliseconds. Of these, 3 were cases of injury to the peroneal nerve; 4 radial; 1 tibial, and 4 ulnar.

In 1 such case of injury to the radial nerve, many Schwann sheath cells arranged pole to pole were seen and a large amount of scar tissue with many lymphocytes was observed. The section showed axon tubes formed by Schwann sheath cells, most of which appeared empty. However, in many places fine, black, thin fibrils could be seen in the structures. They were adjacent to the Schwann cells but definitely separated from them. Especially in the lower end of the nerve structures such fine neurofibrils could be found crisscrossing and invading the surrounding structures (fig. 1). In another case no definite neurofibrils were seen, and in still another a few rudimentary fibers could be seen on cross section as well as extensive formation of Schwann sheath cells.

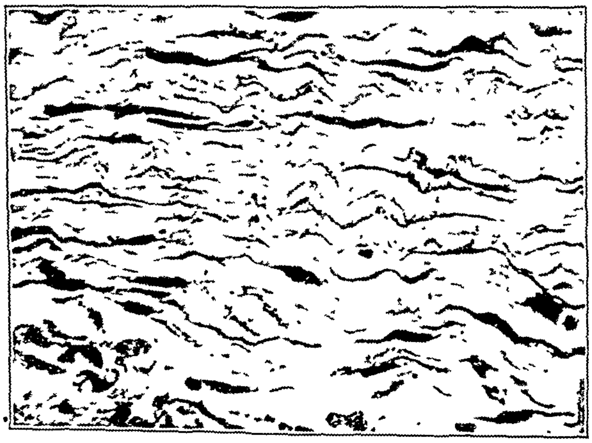

Fig. 2.—Ulnar nerve, with small neurofibrils streaming longitudinally along the Schwann sheath cells (Bodian fuchsin stain).

In 6 cases the muscle supplied by the severed nerve responded to faradic stimulation. Of these, 1 was a case of injury to the median nerve, 3 ulnar, 1 peroneal and 1 radial.

Unfortunately, material was available for histologic study in but 1 instance of injury to the ulnar nerve. In this case pain to deep pressure on the tip of the little finger had also returned. The distal segment was composed of innumerable Schwann sheath cells arranged pole to pole. Many fine fibrils could be seen streaming through the tissue along the Schwann sheath cells (fig. 2).

Of all 69 cases, in only 3 was the galvanic tetanus ratio 1.0. In the other cases the galvanic tetanus ratio was above 1.0, and in some as high as 29.0. In 46 cases examinations of response to electrical stimuli were made at various intervals after resection of the ends of the nerve and suture. In many of these we were unable to show a fall in the galvanic tetanus ratio to 1.0, although in most a considerable fall from the higher preoperative ratio was seen. However, in 18 cases in which the galvanic tetanus ratio had been above 1.0 before operative intervention, after some time it fell to 1.0. In these 18 cases the range of the galvanic tetanus ratio before operation was from 1.6 to 5.8 with a median of 2.5 (fig. 3). There were 4 cases of injury to the median nerve, 4 ulnar, 4 peroneal, 4 radial and 2 tibial. On later examination after regeneration had occurred, the galvanic tetanus ratio again rose, as had been expected. This evolution of changes in the galvanic tetanus ratio (from that characteristic for muscle with varying degrees of innervation to that characteristic of complete denervation, followed by a high galvanic tetanus ratio characteristic of regeneration and ending in many cases with return of motion and sensation) seems to us to constitute proof that severed nerves with separated ends spontaneously regenerate to varying degrees. *Histologic* material was available in 6 of these cases, in all of which varying degrees of development of neurofibrils could be seen in the distal segment. In 1 instance of injury to the median nerve the distal end showed a great amount of scar formation; innumerable elongated Schwann cell elements were present. Along these cells a large number of small fibrils, darkly stained, could be seen. These fibers were *exceptionally fine* and were attached to the Schwann cells but definitely distinct from them (fig. 4).

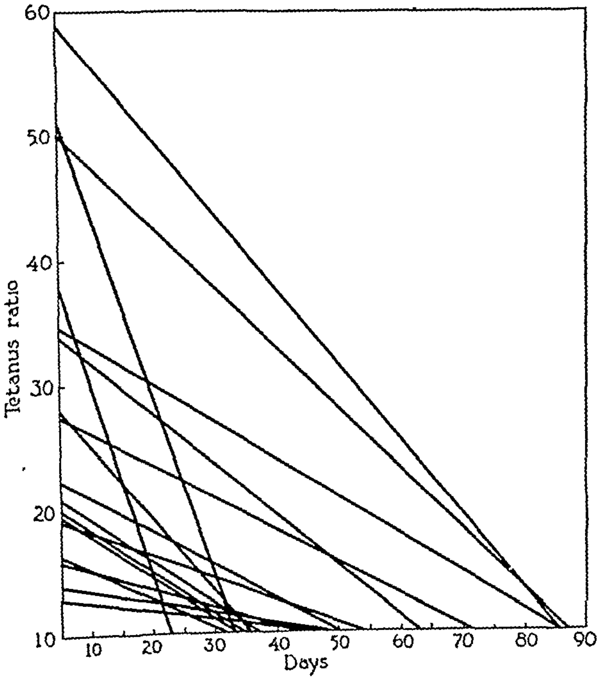

Fig. 3.—Gaps in severed nerves; comparison of preoperative tetanus ratio and denervation of 1.0 at various days after operative intervention.

There were 3 cases of lesions of the ulnar nerve. In 1 the distal part showed a large amount of scar formation. Some neural structures could also be seen which were definitely compressed. A few fine fibrils were present, which reminded one greatly of neurofibrils. They were adjacent to the Schwann sheath cells, were dark and impregnated with black and could be definitely distinguished from the rather plump Schwann cells. In another a large number of Schwann sheath cells were present in the distal segment. They were arranged pole to pole and formed empty tubes. A few fine neurofibrils could be seen in the tissue. They were short and stained a dark black. In the third the distal segment was decidedly small and contained many muscle fibers. In the periphery fine fibrils, which were only lightly stained, could be seen.

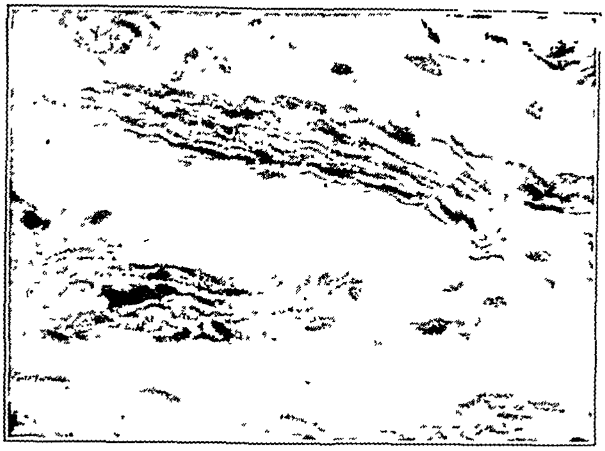

Fig. 4.—Median nerve showing small darkly stained neurofibrils in part of the distal stump.

There were 2 cases of injury to the peroneal nerve. In 1 the peripheral segment showed a diffuse arrangement of Schwann sheath cells. In one area Schwann sheath cells were arranged pole to pole, and fine black fibrils running longitudinally through the specimen could be seen. These fine fibrils were attached to but definitely distinct from the Schwann sheath cells (fig. 5). In the other case a large amount of scar tissue with many lymphocytic infiltrations was present. On longitudinal section a great number of elongated Schwann sheath cells could be seen. Many of these were lying pole to pole, and because of their elongated form they at times simulated neurofibrils in the Bodian preparation. A large number of such structures were present, in most of which no definite neurofibrils could be *distinguished. These Schwann cells formed* axial tubes which seemed to be empty, but there were definitely several areas in which dark, black fibers not connected with the Schwann sheath cells but only attached to them on the outer margins could be seen (fig. 6).

In only 1 case was there a probability of recovery of voluntary motion in an ulnar lesion.

In 3 cases there was a return of pain to deep pressure of the tips of the index or little finger; of the former, 2 were lesions of the median nerve, and of the latter, 1 involved an ulnar lesion. The histology of the lesion of the ulnar nerve has been described (fig. 2).

COMMENT

Although at operation the ends of severed nerves may have been separated by gaps of some distance, prior to surgical intervention there was evidence that nerve fibers had found their way into the distal segment.

This evidence consisted of return of sensation in a few cases, even of motion in 1 instance, and in such response of muscle to electrical stimulus as is indicative that the muscle is not completely denervated. Among the instances of such response were a number of cases with short chronaxia and response to faradic stimulation. In almost all cases there was found a galvanic tetanus ratio of more than 1.0.

Since we have found that the galvanic tetanus ratio of a completely denervated muscle remains 1.0 for as long as we have observed such a muscle, at times for over a year, we consider that we are on safe ground when we conclude that a galvanic tetanus ratio of over 1.0 is indicative of some neurotization of a muscle.

By a fortunate circumstance of having available to us the data obtained before operation and at intervals afterward, we have been able to show that when the preoperative galvanic tetanus ratio was greater than 1.0, at the expected time for denervation after resection and suture of the ends of the severed nerves the galvanic tetanus ratio fell to 1.0.

This we consider to be sound proof that despite long gaps between the severed ends, nerve fibers find their way into the distal segment and muscle. Whether such regeneration would lead to good functional recovery cannot be answered. It is probable that despite evidence of neurotization of muscle or of even return of sensation and motion, good functional recovery would not take place.

In the majority of cases in which tissue was available for histologic examination newly formed neurofibrils were seen in the peripheral segment.

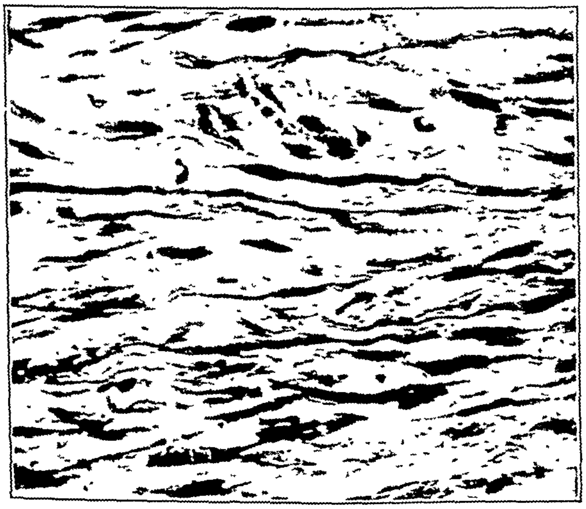

Fig. 5.—Peroneal nerve in which small neurofibrils can be seen attached to the Schwann sheath cells (Bodian fuchsin stain).

In some cases no neurofibrillary structures could be observed. The pathologist, however, was handicapped in the examination of such tissue by the fact that only the most proximal part of the distal stump could be submitted. These structures lying so close to the injured section of the nerve are always surrounded by a tremendous proliferation of connective tissue, and in many cases innumerable lymphocytes are also present. Fine fibrillary structures may conceivably be destroyed in such mediums or may easily escape attention.

It is conceivable that if a section could be made through the more peripheral parts of a severed nerve fibrillary structures might be seen.

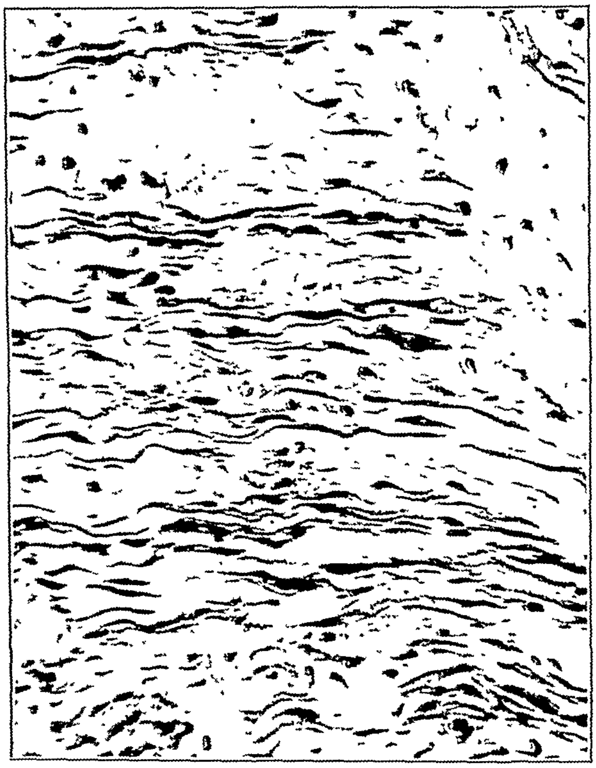

Fig. 6.—Peroneal nerve with small, darkly stained fibrils passing longitudinally along the Schwann sheath cells.

Moreover, there is a suggested possibility that some fibers may break through from adjacent nerves and find their way to the distal segment of the severed nerve being studied.

In electrodiagnosis, evidence of neurotization as shown by short chronaxia, response to faradic current and a galvanic tetanus ratio above 1.0 must be evaluated along with other evidence of recovery in relation to the time which has elapsed since injury. When a sufficient time has elapsed after injury so that maturation would be expected to be well advanced, signs limited to those obtained by electrical stimuli constitute evidence of a minimal neurotization.

CONCLUSIONS

1. At the time that gaps of varying lengths between ends of severed nerves have been found on operative intervention, there has been evidence that fibers had found their way to the distal segment. This evidence consisted of: in a few instances, a return of sensation; in a considerable number, a short chronaxia and response to faradic stimulation of muscle, and in most, a galvanic tetanus ratio of over 1.0.

2. Histologic examination revealed the presence of neurofibrils in the distal segments of the severed nerve.

3. Spontaneous regeneration, probably of insufficient degree to result in recovery of function, occurs to some extent in most instances of severed nerves.

RIGHT-SIDED (REGIONAL) COLITIS

BURRILL B. CROHN, M.D.
JOHN H. GARLOCK, M.D.
and
HARRY YARNIS, M.D.
New York

Eight per cent of all cases of ulcerative colitis of the nonspecific type are regional or right sided in anatomic distribution. They represent a distinctive subgroup, inasmuch as by sigmoidoscopic examination the rectum is free of disease. In this subgroup the pathologic process begins and is commonly limited to a segment or segments of the proximal colon; its life history is characterized by a progressive march to the left, until by skip lesion or by continuity the whole colon from cecum to sigmoid may become interruptedly or continuously involved.

Clinically right-sided or regional or segmental colitis is less severe in its local signs and symptoms than is universal or left-sided colitis with its predominantly rectal involvement; that is the diarrhea, the urgency, the straining and the bloody stools are less pronounced. On the other hand, the constitutional manifestations are more apparent and are characterized by fever, often continuous, by manifestations referable to the joints, ocular complications and occasional implication of the valves of the heart.

Table 1.—*Right-Sided (Regional) Colitis; Seventy-Seven Cases to September 1945*

Sex			
Male	Female	Age: 1 to 60 Years	Cases

Involvement of terminal ileum..................	33

Segmental colitis is progressive in nature and in anatomic distribution, but lends itself well to surgical approach in the nature of short-circuiting procedures followed by resection of the diseased proximal areas.

Segmental colitis without involvement of the rectum, while not a new entity, has not received the clinical attention and the recognition that the subject deserves. Bargen and Weber[1] had reported 23 such instances in 1930, Crohn and Berg[2] 17 cases of regional colitis in 1938, 14 of which had been subjected to surgical procedures. Bargen in 1939 classified as regional in distribution 6.3 per cent of 299 cases of ulcerative colitis observed at the Mayo Clinic up to 1939. Bockus[3] speaks of the regional type of colitis as being estimated generally as between 5 and 15 per cent of all such cases. The office records of one of us (B. B. C.) includes 600 cases of ulcerative colitis of which 48 or exactly 8 per cent are segmental or regional in distribution.

This study comprises 77 cases of right-sided or segmental colitis which have come under our observation between the years 1928 and the present date, namely seventeen years with an assiduous follow-up which necessarily varies by many years but which is accurate and recent and which covers all but 2 of the cases, which have been lost to record. The causation of this form of colitis is as little specific or known as that of colitis in general or of ileitis. Specific pathogens have as yet not been determined. Tuberculosis and syphilis play no role. The Shigella of dysentery has been impugned, but in our cases all cultures of the stool and of the wall of the intestine have been negative and in the few cases in which specific dysentery agglutinins in the serum have been sought, no distinctive titers have been found. The observations and studies of Reimann[4] with the demonstration of a filterable virus in cases of so-called nonspecific or indeterminate diarrhea is to our recollection the first successful attempt to associate a virus with any form of diarrheal disease, exclusive of venereal lymphogranuloma. This work with its suggestive observations points the way to a possible elucidation of the causation of many indeterminate intestinal infections.

The age distribution in segmental colitis is much like that of universal colitis and ileitis. The average age at the time of study has been 27.3 years; the youngest patient was 6 years, and the oldest 60 years of age. All the intervening decades are represented, the main incidence being 33 cases during the third decade of life (20 to 30 years) and 14 cases in the fourth decade (30 to 40 years). Women predominate somewhat in this group, the proportion being 45 women to 32 men (table 1).

ANATOMIC DISTRIBUTION OF THE DISEASE

The pathologic process involves one or many of the segments of the colon in its progressive course except the rectum. Cases in which the rectum has already become involved by late extension have been excluded from this study and have been grouped as instances of universal colitis even though the process originated in the right rather than in the distal colon and the rectal and the rectosigmoid segments. Since surgical intervention has been called on in all of this series to delimit disease before the rectum was implicated, the discussion of anatomic distribution is necessarily restricted to the proximal colon.

Pure "right-sided" colitis involving the cecum and the ascending colon was observed 22 times (table 2). The transverse colon and the descending colon alone were regionally involved in 16 cases. In the remaining 39 instances all of the proximal colons from the cecum to the sigmoid were either continuously involved or were affected by intermittent "skip" lesions. Associated involvement of the terminal ileum was noted in 33 of the cases, these being characterized by excessive severity in the clinical course, the ileitis occurring by backwash extension from the cecal areas of involvement. Rarely is the ileum the sole and primary source of the disease, though often, when first observed, the terminal ileum and several "skip" areas in the proxi-

mal colon are already demonstrable roentgenologically or at exploratory laparotomy. These cases of combined ileitis and colitis (ileocolitis) are among the gravest which have come under our observation.

CLINICAL MANIFESTATIONS OF SEGMENTAL COLITIS

The clinical manifestations of segmental colitis (table 3) are both local in the intestinal tract and general throughout the body. Locally the disease is characterized by diarrhea which is rather moderate in severity, two to three or up to five to seven stools per day, the stools being mushy or liquid or mucoid in character, fresh blood being rarely present. The straining, the urgency and the extreme frequency of defecation with watery sanguineous stools as seen in left-sided or universal colitis are not present, essentially because of the absence of involvement of rectum and the rectal and anal sphincters Occult blood in the stools may or may not be present and is an undependable sign Gross hemorrhage either at the onset or during the course of the disease occurred seven times, the hemorrhage being frank and profuse, but never seriously threatening life and easily controlled by opium derivatives and by liberal administrations of synthetic preparations of vitamin K.

The bowel movements are usually preceded by abdominal pain localized to the lower segments of the abdomen, particularly the right lower quadrant The sequence of events is pain, urge to defecate, defecation and relief, a sequence which is characteristic both for right-sided colitis and for terminal ileitis Intestinal obstruction occurred twice in this series, once as an initial and severe manifestation and once as a sequel to a long-standing case in which there had been refusal over a course of years to accept surgical intervention. In this type of segmental colitis rectal complications are again common (table 4). In this series of 77 cases anal fistulas occurred fifteen times; perirectal abscesses without fistulas four times, and rectovaginal fistulas twice; in 1 of the latter 2 cases the fistula closed spontaneously after a resection of the involved proximal colon. In addition we noted 1 internal fistula (colon to ileum) and 2 fecal fistulas to the anterior abdominal wall. It is of interest to note that though the rectum and the anus are not part of the inflammatory process, still the same prodromal and accompanying complications occur here as in ileitis. The infectious agent is transported from the above involved areas through the sigmoid and the rectum, to lodge presumably in the crypts of Morgagni, there to reenact the sequence of infection, abscesses and fistulas As a rule, perianal or perirectal phenomena do not complicate any of the nervous or functional diarrheas, the allergic diarrheas, or those classed as mucous colitis or irritable bowel. The presence of perianal abscesses or fistulas thus differentiates the infectious and organic from the functional varieties of intestinal disturbances.

General Manifestations—Among the general manifestations of the disease, fever is the most outstanding, being present in 49 out of the 77 cases The febrile course, ranging from 101 to 105 F., is irregular in form, lower in the morning and higher at night and not continuous and sustained but irregular and peaked. It is commonly present and characterizes the cases of more severe disease and signifies phases of active progression of the pathologic process The afebrile type is less severe, is indolent and represents the inactive or chronic nonprogressive phase of the process

The leukocyte count is usually low or only slightly elevated (8,000 or 12,000 to 15,000); rarely, except in cases of extremely toxic disease, is it as high as 25,000. The diarrhea being often minimal if not occasionally absent, these cases of fever of unrecognized origin are frequently confused with those other clinical conditions which are themselves characterized by continuous fever with low white cell counts and few if any localizing symptoms. Segmental colitis in which the diarrhea is minimal or has been overlooked is frequently confused with brucellosis, with chronic rheumatic fever, with subacute bacterial endocarditis, with periarteritis nodosa or with the Libman-Sacks form of disseminated lupus erythematosis. Such a case of long-standing fever with multiple involvements of the joints, simulating for a long period rheumatic fever, has been aptly described in the recent literature by Sprague, Anderson and Aaron.[5]

Segmental colitis is, however, marked by its general symptoms apart from the diarrheal manifestations. These general symptoms consist of single or multiple involvement of joints, by a variety of ocular manifestations, by the occurrence of aphthous ulcerative stomatitis, by erythema nodosum on the extremities, by occasional involvement of the heart valves and again locally by its most frequent complication, perianal fistulas and abscesses

Involvement of the Joints.—Monarticular, but more commonly polyarticular, involvement is common. Any of many of the larger joints (elbows, knees or ankles) may be affected; the smaller joints, particularly of the hand, are frequently the site of periarticular inflammation The joints are slightly enlarged, tender and painful, the periarticular serous membranes being more implicated than the serosal lining of the joint proper. Involvement of joints, seen frequently in the diffuse or universal type of ulcerative colitis, is not seen in ileitis or in ileojejunitis. Its true prototype is observed in bacillary dysentery; this has long been recognized and has been aptly termed "dysenteric rheumatism." Clubbing of the fingers occurred twice in this series, an occurrence which is significant of serious metabolic and nutritive disturbances.

[5] Sprague, P H, Anderson, W S, and Aaron, T. H: Long Standing Fever Due to Regional Ileo-Colitis, Am J. Digest Dis 11: 295 296 (Sept) 1944

Ophthalmologic Complications.—One of the less frequent but characteristic complications is involvement of the eye as part of a focal infection. Phlyctenular conjunctivitis, iritis, keratitis and uveitis constitute the commoner forms. All these manifestations of focal infection are also commonly seen in universal ulcerative colitis, either as inflammatory or as avitaminotic sequelae. Where the diarrhea is exaggerated and severe, the eye complications seem of secondary importance. But when, as in this type of colitis, the diarrhea is minimal and fever is the sole evidence of an infection, then the involvement of the eye together with joint inflammations constitute a very significant guide to diagnosis.

Involvement of the Heart.—In 1 case we noted an acute endocarditis, with fever and a blowing systolic apical murmur developing under observation. The temperature was high and the patient prostrated, but the blood culture at the height of the febrile curve was negative. With the patient under intensive therapy with penicillin the temperature dropped to normal within five days and the cardiac murmur disappeared. The segmental colitis persisted in spite of the penicillin and required subsequent surgical resection.

In the cases of more chronic disease one not infrequently meets with old so-called rheumatic valvular heart disease. This occurred twice in our limited series of cases (77) and probably represents a pure coincidence of two unrelated diseases. It would, however, be interesting to hypothecate a specific type of chronic valvular disease of the heart arising solely as a complication of this type of segmental colitis and not related to a previous rheumatic origin.

Cutaneous Manifestations.—In this series erythema nodosum occurred twice, the rash being identical with that on the extremities so commonly observed in the severe types of universal colitis. A purpuric rash was once seen, possibly as a sequel to the use of the sulfonamide drugs. Stomatitis occurred three times.

DIFFERENTIAL DIAGNOSIS

The diagnosis of segmental colitis is simple once one becomes conscious of the fact that colitis can and does occur even though the sigmoidoscopic examination is negative. The roentgenograms taken after a barium enema, when interpreted by an experienced eye, should demonstrate disturbed mucosal pattern, irregular and moth-eaten borders of the outline of the colon, foreshortening of the lumen and absence of haustral markings in the affected segments of the large bowel. The roentgenographic interpretation is usually anatomically accurate; the diseased areas as noted in the roentgenograms correspond anatomically rather accurately with the bowel as seen at time of operation or in the resected specimens.

In the absence of diarrhea, or when the diarrhea is so minimal as likely to be overlooked in the more impressive array of general symptoms the diagnosis of segmental colitis becomes a more difficult problem. When fever, articular manifestations and ocular complications (iritis, uveitis) are the obvious clinical symptoms, it is easy to understand why so frequently these cases are mistaken for chronic rheumatic fever, for Libman-Sacks disease, brucellosis or periarteritis nodosa. The leukocyte count is generally low in all of these clinical conditions; the fever is similarly frequently continuous or irregular in type. But diarrhea, which is not present in any of these complicated symptom complexes, an astute observer will usually find almost regularly present in segmental colitis. The agglutination titer of brucellosis is absent, though the course in segmental colitis may be equally prolonged and irregularly febrile. The cutaneous manifestations of lupus erythematosis disseminatus are absent, as well as the late general involvement of the arteriolar tree and the renal parenchyma. The eosinophilia of periarteritis nodosa is absent as well as the late renal albuminurea and evidences of arteriolar degeneration.

It behooves every internist to watch carefully any case of fever of supposedly unknown origin, lest by disdaining to note the mild diarrhea, the vague abdominal pain or the perianal complications, he may fail to recognize and identify the focus of origin of the disease in this segmental form of ulcerative colitis.

The differentiation of right-sided colitis from terminal ileitis or ileojejunitis is essentially a roentgenographic one. Articular and ocular manifestations are rare in ileitis, fistulas of the abdominal wall common. The "string sign" of terminal ileitis in its classical appearance does not occur in segmental colitis. Combined forms of right-sided colitis (cecum and ascending colon) with extension into the terminal ileum occasionally occur. Presumably the original or parent site of the lesion is the colon, for though the colitis may continue to spread and extend toward the anus the ileitis remains stationary; skip lesions in the upper part of the ileum do not occur.

Recurrences, when seen after surgical resection or short-circuiting procedures invariably occur in the more distant parts of sigmoid and rectum and not in the proximal part of the ileum.

PROGNOSIS AND MEDICAL TREATMENT

In right-sided or segmental colitis the prognosis is "good." Whether by medical or by surgical skill the patient may expect to be restored to good health and efficiency. Of the 75 patients seen and observed in the follow-up, 63 are alive, a total survival rate of 84 per cent (16 per cent mortality).

A group of 19 patients remain under medical or conservative observation; 12 are well, 3 improved and 4 unimproved. These patients chose and insisted on conservative therapy, such treatment consisting of a strict nonroughage diet, bed rest, abstention from vigorous exercise, and the intramuscular injection of large doses of the various vitamin fractions. Three lines of approach in therapy are instituted.

Retention enemas of 1 to 4,000 solution of neutral acriflavin in isotonic solution of sodium chloride, 350 cc. to be retained, are given each night at bedtime. Chemotherapy, that is, the administration of the less soluble sulfonamide compounds, is regularly prescribed. Succinylsulfathiazole in the dosage of 0.25 Gm. per kilogram of body weight is from experience a good therapeutic agent. Thus a man of 130 pounds (59 Kg.) of body weight will take thirty tablets as an initial dose and seven to eight tablets four times daily thereafter. If succinylsulfathiazole proves ineffectual, the new phthalylsulfathiazole, ten tablets daily, should be recommended. There are few local or general reactions to these relatively insoluble sulfonamide derivatives; if the hemoglobin is watched every few days for possible hemolytic anemia, if no rash appears or further rise of temperature, the sulfonamide drug may be indefinitely continued. Finally, intramuscular injections of 1 cc. of crude liver extract and vitamin B complex should be given every other day.

Under this form of conservative therapy 12 of the 19 medically treated patients are well and have remained well. It would be erroneous to conclude from this figure that 12 out of 19 or approximately 63 per cent of the whole group of patients would have shown improvement or cures by such a conservative plan of therapy. All of the larger group of patients who submitted to surgical treatment must be deemed "medical" failures, for they presumably had had previous conservative treatment, submitting to operation only as a recourse from the failure of such an attempted therapeutic regimen.

In the over-all picture, therefore, 12 "cured" out of a total of 77 patients represents a medical success of only 15.6 per cent. Even so, the fact that 12 persons in this relatively small group preferred medical treatment and were restored to health indicates that there is a field for conservative therapy which warrants a trial before the more brilliantly successful but more arduous and less safe approach of surgical intervention is chosen.

SURGICAL CONSIDERATIONS (DR. JOHN H. GARLOCK)

On the basis of our experience with these 77 patients, we are now agreed that in the cases of milder disease a trial should be made of medical therapy but that most of the patients will necessarily be subjected to surgical treatment. With a disease the exact course of which is still unknown, it has been extremely difficult to predict what would happen to the uninvolved lower part of the sigmoid and the rectum subsequent to the removal of the diseased colon. The observations of the clinical course of a few cases of severe disease in which surgical therapy was refused has led us to believe that the disease progresses from right to left in a steady march and eventually will involve the rectum. If this progression is permitted to occur, then all hope of restoring normal intestinal continuity will probably be lost. Permanent ileostomy then becomes the only recourse. It is because of these observations on the life history of the disease that we have formed the opinion that the majority of these patients should be treated by surgical means. It remained for careful follow-up study to indicate what would eventually happen to the uninvolved rectum and it is the purpose of this section to indicate what these studies have shown.

The surgical treatment of segmental or right-sided colitis as evolved in our clinic is predicated on the fact that there is no evidence whatsoever of any disease in the rectum and/or the sigmoid. To be certain of this requires repeated sigmoidoscopic examinations and careful barium enema roentgenographic demonstrations of the large bowel. The slightest swelling or friability of the rectal mucosa should deter the surgeon from carrying out any anastomosis. If rectal mucosal swelling or friability is demonstrated, then the plan of surgical attack must be altered. Under such circumstances, the first operation should consist of ileostomy, followed, three to six months later, by subtotal colectomy. Experience with an appreciable number of such cases has shown that after the removal of the seriously diseased colon the rectal mucosa will quickly return to normal and that it will then be possible to reconnect ileum and the upper part of the rectum, thus restoring intestinal continuity.

If, however, the rectum and/or the sigmoid are found to be normal, the surgical treatment consists of a two stage operation. The first operation is carried out through a long incision in the lower part of the left rectus. Exploration will indicate the extent and severity of involvement of the colon. Usually, the diseased bowel is thickened and foreshortened and the serosa displays a reddened stippled appearance. The regional lymph nodes are enlarged and succulent. Too much handling of the bowel is inadvisable. It will be found that the disease ends abruptly and that there is a fairly sharp line of demarcation between the involved portion and the normal distal segment. The examination should also include the terminal part of the ileum to demonstrate the presence or absence of "backwash" ileitis. The patient is now placed in high Trendelenberg position. The terminal part of the ileum is divided about eight inches (20.3 cm.) from the cecum after section of its mesentery and accurate ligation of the vascular arches. Sufficient mobility of the proximal loop should be obtained in order to permit of its approximation to the rectum deep in the pelvis, should that become necessary. Both ends of ileum are triply inverted with silk sutures and the distal one is dropped into the abdomen.

Attention is now directed to the distal colon. The exact termination of the disease process should be determined. This may be anywhere along the transverse or left part of the colon, and in many instances it may extend to the distal portion of the sigmoid. At an appropriate distance beyond this point the mesocolon is split from its base to bowel attachment with accurate ligation of the vessels in the line of incision. Care should be taken to ligate the marginal artery at the same level of bowel division in order to protect the blood supply of the ends of the bowel. The reason for complete division of the mesocolon is twofold: first, in order to obtain adequate mobilization of the proximal loop for exteriorization without tension and, second, to cut across all possible lymphatic channels on the theory that these may be factors in the progression of the disease distally; the latter is purely theoretic. The colon is now divided between appropriate clamps and the proximal part of the colon is brought out through the abdominal wall for exteriorization. This is done to allow for external drainage of the foul discharge that comes from the diseased segment. The distal end of the transected colon is now carefully inverted with three layers of silk. The proximal ileal loop is approximated to the lower sigmoid or anterior rectal wall, as the case may be, and an isoperistaltic side to side anastomosis effected. The cut edge of the mesentery of this loop of ileum should be tacked down to the posterior parietal peritoneum to prevent herniation of small bowel beneath it. The abdominal wound is closed about the exteriorized proximal limb of colon with buried wire sutures and skin clips. On the third or fourth postoperative day the clamp on the exteriorized loop should be removed. Prolonged application of this clamp may lead to a blowout of accumulated secretions in the region of the cecum.

During the succeeding three or four months, there will be usually noted a dramatic change in the general condition of the patient. The gain in weight may be up to 50 pounds (22.7 Kg.). During the early stages of convalescence the patient may be troubled by multiple liquid movements, but, as time goes on, compensation for the disturbed intestinal functions takes place and most of the patients eventually have only one to three formed movements. The articular symptoms and ocular and cutaneous manifestations may not clear up until the diseased part of the colon is extirpated. Certainly the fever abates, and otherwise the patient is clinically well.

The second stage is carried out when the limit of improvement has been reached, and this is usually after three or four months. This second procedure consists of a subtotal colectomy, performed through a long incision in the right rectus. Before the incision is made, the exteriorized limb is freed from the abdominal wall, closed over with silk and dropped into the abdomen. The colectomy is done in the usual manner, but we have made a great effort carefully to peritonealize all raw surfaces to prevent late intestinal obstruction In the early days of this work, this was a serious complication. However, since we have insisted on complete peritonealization there has been a sharp drop in the incidence of late obstruction This point deserves emphasis.

Table 5—*Surgical Therapy*

Type of Operation	Number of Patients	Operative Mortality
Ileotransverse colostomy with exclusion of ileum	2	0
Ileotransverse colostomy with subsequent ileocolic resection	6	0
Ileosigmoidostomy with exclusion of ileum	12	5
Ileosigmoidostomy with subsequent subtotal colectomy	32•	7
Ileostomy with subsequent colectomy and reanastomosis	4	0
One stage ileocolic resection	2	0
Total	58	12

Operative mortality 20%

In the group of 58 patients treated surgically, 3 were operated on elsewhere but came under our observation and are included for completeness. The accompanying table 5 is self explanatory and indicates the type of operation in each group and the mortality incidence. If we exclude the 3 fatal cases in which operation was done elsewhere, our own series would be 55 patients with 9 deaths or a 16.2 per cent mortality.

It will be noted that 14 patients had either ileotransverse or ileosigmoid anastomoses with exclusion of the ileum as the only definitive procedure. Most of these were in the early group of this series. On the basis of subsequent experiences, we believe that the short-circuiting operation should include division of the part of colon proximal to the new anastomosis with exteriorization of the proximal end and resection of the excluded part of the bowel at the second stage.

Table 6—*Analysis of Operative Deaths*

Cause of Death	No of Cases
Sulfanilamide hepatitis	1
Postoperative shock (operations done elsewhere)	2
Peritonitis (1 case done elsewhere)	5
Pulmonary embolus	1
Perforation of cecum with peritonitis	1
Retroperitoneal phlegmon	1
Undiagnosed subhepatic abscess	1

This, we feel, is the procedure of choice, and it was carried out in 44 instances.

An analysis of the causes of death reveals some interesting facts. In the majority of these 12 cases, postmortem examination was carried out Table 6 indicates that the major cause of death was peritonitis. Here again, 4 of these patients were operated on in the early days of this study. With increasing experience, it becomes evident that these patients should have had an ileostomy as the first operation. They were all too acutely ill to warrant the extensive procedures that were carried out. Two patients died of postoperative shock; both had been operated on elsewhere. One patient died of peritonitis due to postoperative perforation of the cecum, which had been handled with a sponge at the time of operation. This case emphasizes the need for great care in the operative manipulation of the colon, especially in the acute and subacute cases. With the advent of the newer antibiotics, with more thorough preoperative preparation and with increasing experience in the selection of the suitable operation for the problem at hand, there has been noted a rapidly decreasing operative mortality in the past two years. We are confident that this mortality will reach the present low figure for operation for cancer of the colon.

Follow-up Studies.—The greatest interest in this study has been in determining the subsequent course of the 46 patients who survived operation, especially with respect to function of the bowel and the development of disease in the remaining part of the colon and the rectum. All cases have been followed for at least six months (table 7). Most of the patients in this series have been under observation for an average period of almost three years after the termination of surgical therapy. One patient has been followed for sixteen years. The average weight gain was 30 pounds (13.6 Kg.). Following resection of the colon, all manifestations cleared spontaneously. Of the 43 patients who have remained well, all except 4 have an average of three formed movements daily. The remaining 4 have five or six semiformed stools a day with occasional bouts of mild diarrhea. The most important feature of this study has been the fact that, of 46 survivors of operations only 3 subsequently experienced disease in the rectum In these 3 instances an ileostomy was perforce performed. Two of these patients died and are included in the mortality chart One patient survived and is awaiting reconnection of his ileum The remaining 43 patients are clinically well and carry on a normal existence.

Table 7—*Follow-Up Results*

16 Years to 6 Months—46 Operative Survivors

Type of Operation	Well	Unimproved	Subsequent Disease in Rectum
Ileotransverse colostomy with ileal exclusion	2	0	0
Ileotransverse colostomy with subsequent ileocolic resection	5	0	1
Ileosigmoidostomy with ileal exclusion	7	0	0
Ileosigmoidostomy with subsequent subtotal colectomy	24	0	1
Ileostomy with subsequent colectomy and reanastomosis	3	0	1
One stage ileocolic resection	2	0	0
Total	43	0	3

We believe, on the basis of this group study, that segmental colitis is quite different from universal ulcerative colitis in its clinical course, diversified manifestations and response to definitive surgical therapy. In the vast majority of instances, the prognosis is good and the patient can be restored to normal health. It is felt that the radical surgical therapy outlined in this paper offers the greatest hope to a majority of the sufferers of this disease.

ORAL ADMINISTRATION OF PENICILLIN IN CHRONIC ULCERATIVE COLITIS

A Clinical, Chemical and Bacteriologic Evaluation

MICHAEL H. STREICHER, M.D.
Assistant Professor of Medicine, University of Illinois
College of Medicine
Chicago

In the past few years considerable progress has been made in the treatment of chronic ulcerative colitis with the newer intestinal sulfonamide compounds. Phthalylsulfathiazole has been very effective. Essentially, therapeutic results were obtained through the action of sulfonamide compounds against the coliform organisms plus the standard supportive measures.

The sulfonamide compounds employed in infectious disease of the colon failed to be efficacious against the staphylococci and the streptococci.

With the present knowledge of penicillin and its properties it was thought advisable to employ this agent alone and in combination with phthalylsulfathiazole in chronic ulcerative colitis.

The recognition of penicillin as a general antibacterial agent came with the experiments of Fleming[1] in 1929. His researches were corroborated by Reid[2] in 1935 and by Bornstein[3] in 1940. Later the studies were extended in reference to stability by Chain,[4] Florey[5] and Clutterbuck.[6] Abraham,[7] in his studies on staphylococci, concluded that penicillin exerted only a bacteriostatic effect, while Rantz and Kirby[8] suggested that its action is bactericidal. Hobby, Chaffee and Meyer[9] concluded that this antibiotic has both bactericidal and bacteriostatic action and that activity depends on experimental conditions. The first clinical report, made by Florey and his co-workers in 1941, was on an Oxford policeman who had a Staphylococcus aureus and Streptococcus pyogenes infection.

Primarily the power exerted by penicillin is against gram-positive bacteria, whether aerobic or anaerobic, and yet it does possess some antibacterial properties against most gram-negative organisms. Fleming[1] also reported variations in sensitivity in some strains of the green-producing streptococci; he also stated that penicillin is relatively ineffective against organisms of the colon-typhoid group.

Wide variations in sensitivity of strains were reported by Heilman and Herrill,[10] Bornstein,[3] Spink[11] and Rammelkamp and Maxon.[12] The staphylococci are highly sensitive to penicillin and are more uniform in their strain variations.

PROCEDURE OF STUDY

Forty-five patients afflicted with chronic ulcerative colitis were employed in this study; of these 6 were males and 39 females. All were studied clinically and proctoscopically.

Penicillin was administered orally to each patient in doses varying from 100,000 units to 300,000 units daily. A calculated amount of phthalylsulfathiazole was given to some subjects simultaneously. The patients were hospitalized for two weeks and controlled during the experimental trial. Recovery of penicillin was determined daily in the blood, urine and stool. The level of phthalylsulfathiazole in the blood and stool was also established.

Bacteriologic studies and sensitivity studies were made before and after treatment.

RESULTS

Bacterial Response.—The bacteriologic response in the stool to oral administration of penicillin is significant in that a definite trend is noted in the B. coli count on the one hand and the staphylococcus and streptococcus counts on the other.

Table 1.—*Bacterial Response to Penicillin Administered Orally in Chronic Ulcerative Colitis*

Number of Patients	Dosage in Units	B. Coli		Staphylococcus		Streptococcus	
		Before	After	Before	After	Before	After

* Bacterial count in millions.

For instance, with a daily dosage of 100,000 units of penicillin orally the B. coli count was recorded as 96,000,000 before treatment and 3,390,000,000 four days after treatment; the staphylococcus count was decreased from 433,000,000 to 50,000,000 and the streptococcus from 180,000,000 to 60,000,000 over the same period. With a dosage of 300,000 units daily the B. coli count ranged from 68,000,000 to 279,000,000, while the staphylococcus count decreased from 100,000,000 to 6,000,000 and the streptococcus from 5,000,000 to 57,000.

When phthalylsulfathiazole is given simultaneously in doses varying from 1.5 Gm. to 3 Gm. daily the B. coli, the staphylococcus and the streptococcus counts are decreased correspondingly.

These results are exemplified in detail in tables 1, 2 and 3.

It was observed that twenty-four hours after administration of penicillin the staphylococci and the streptococci register an initial rise in number and subsequently decrease to a level below the original.

The research grant on oral penicillin is sponsored by Sharpe and Dohme, Glenolden, Pa.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

Assistance was given by Miss Verna Pittard, research assistant, and helpful suggestions were made by Dr. Robert W. Keeton, Head, Department of Medicine, and Dr. Milan Novak, Head, Department of Bacteriology.

Sensitivity of Bacteria to Penicillin.—To determine sensitivities of organisms found in the stool, typical colonies of representative types were picked out, incubated and inoculated into broth. Then serial dilutions of penicillin were made in brain broth. The number of units of penicillin required to inhibit growth of an organism is then determined by a modification of the Rammelkamp technic.

TABLE 2.—*Bacterial Response to Penicillin Administered Orally in Chronic Ulcerative Colitis*

Number of Patients	Dosage in Units	B. Coli		Staphylococcus		Streptococcus	
		Before	After	Before	After	Before	After

			63	...	0 4	.	0 1
			301	...	5	..	0 1
			279	...	6	..	0 05

* Bacterial count in millions.

In the coliform group the sensitivities ranged from 20 to 80 units after treatment. When phthalylsulfathiazole was used in addition to penicillin administered orally the sensitivities ranged from 100 units before treatment to 350 units after treatment. The staphylococci and the streptococci respond in the same direction (as shown in table 5).

Determination of Penicillin Levels in the Blood, Urine and Stool.—Blood levels of penicillin were determined daily by the method of Cooke and also by the Kolmer modification of Rammelkamp's method. Blood samples were drawn at 4 p. m., when maximum concentrations were assumed; these were collected sterilely, and penicillin assay was made after the cells had settled by centrifugation. The levels ranged from 0.1 unit to 0.4 unit per cubic centimeter, as shown in table 4.

The urine is collected into sterilized bottles and corked. The specimens were collected at 9 a. m., 1 p. m. and 4 p. m. and refrigerated until assayed. Urine levels ranged from 0.4 unit to 100 units of penicillin per cubic centimeter, depending on the dose of penicillin on oral intake (table 4).

TABLE 3.—*Bacterial Response to Penicillin Administered Orally and Phthalylsulfathiazole in Chronic Ulcerative Colitis*

Number of Patients	Dosage	B. Coli		Staphylococcus		Streptococcus	
		Before	After	Before	After	Before	After

			4 8	..	106	..	74
			5 2	..	73	..	43
			4 1	..	302	..	94
			4.7	..	313	..	199
			4 2	..	194	..	126

* Bacterial count in millions.

The assay in the stool is done by a modification of the method of Cooke; the specimen is refrigerated immediately on collection and after a sterile filtrate is obtained the procedure is similar to that used in determining the penicillin levels in the blood and urine as shown in table 4.

The penicillin levels in the stools ranged from 0.4 unit to 80 units per gram.

Clinical Studies.—The clinical study was carried on for one year. Of the 45 patients treated orally with penicillin 39 were female and 6 were male; of these 40 were in the chronic stage and 5 in the acute stage. The entire group showed improvement with oral administration of penicillin in doses of 100,000 to 300,000 units daily. One is impressed with the fact that the cramping in the abdomen subsides and that the number of evacuations are reduced. The stools become formed but are *not* odorless, and the blood and pussy mucus is reduced considerably. The temperature is lowered to some extent after treatment has been continued for four days or more. No toxic signs or symptoms were elicited in any patient after oral administration of penicillin from one to four weeks in doses varying from 100,000 to 300,000 units daily.

When phthalylsulfathiazole was administered in addition to penicillin, the most gratifying observation was that of the disappearance of the odor in the stool and with that the change in the color of the stool to a lighter yellow.

These patients were studied proctoscopically after treatment, but apparently not enough time has elapsed to evaluate the changes noted.

COMMENT

Much has been written on the oral administration of penicillin and the method has been in disfavor because penicillin is inactivated by the acidity in the stomach. It is also claimed that it is destroyed in traversing the gastrointestinal tract by body heat and that it would prove ineffective unless the penicillin were absorbed before passing the upper intestinal tract and thus escape its destruction by the bacteria in the colon.

Libby [13] administered penicillin orally successfully and concluded that larger doses would be needed to produce comparable blood levels.

The destruction of penicillin by penicillinase-producing organisms reported by Abraham and Chain [7] is not conclusive inasmuch as it has been shown that absorption of penicillin occurs from ligated loops of the colon in the rat.

In my experience oral administration has proved efficacious—because while it may not have proved to be specific against B. coli it has been decidedly active against staphylococci and streptococci; this would indicate that the quantity of penicillin that reached the colon was not inactivated entirely either by the gastric juice, the body heat or the penicillinase-producing organisms.

---

[13] Libby, R L: Oral Administration of Penicillin in Oil, Science **101:** 178 180 (Feb 16) 1945.

Again, our results on the concentration of penicillin in the stool (table 4) show that substantial amounts of orally administered penicillin reach the colon effectively.

While the literature does stress the fact that the power exerted by penicillin is primarily against gram-positive bacteria, my results show that B. coli may be inhibited in the stool by 80 units when 100,000 units or 150,000 units of penicillin are administered orally for two weeks, and that B. coli may be inhibited by 20 units when 225,000 units are given orally for ten days.

This antibacterial trend by penicillin against gram-negative bacteria is impeded when phthalylsulfathiazole is added; when 3 Gm. of phthalylsulfathiazole is given in addition to 225,000 units of penicillin 300 units are needed to inhibit the B. coli organisms, as against 20 units when penicillin is given alone.

The staphylococci of the albus group and the streptococci of the gamma type are readily susceptible to penicillin; when, however, phthalylsulfathiazole is given with penicillin the staphylococci (albus) and the streptococci (gamma) become less sensitive, as is demonstrated in table 5.

It is worthy of note that the elimination of penicillin in the urine is decreased when phthalylsulfathiazole is given in addition to penicillin administered orally. This tendency would indicate that phthalylsulfathiazole brings about a slower rate of absorption of penicillin or prolongs the retention of penicillin in the body in a way similar to that of para-aminohippuric acid (excretory blockade).

I should like to refer to the work of Bigger,[14] who concluded that sulfathiazole is more effective than other sulfonamide compounds in combination of sulfonamide compounds with penicillin.

The work of Bigger on the synergic action of penicillin and sulfonamide compounds is corroborated in my studies on chronic ulcerative colitis. Because this disease is a polyvalent infection the combined utilization of both therapeutic agents has proved effective.

The evidence which I present suggests that if oral administration of penicillin could be made practicable, large doses would be required and correspondingly large amounts of penicillin would be wasted.

To obtain the maximum effect with a limited quantity of penicillin the combined utilization of penicillin and phthalylsulfathiazole would be preferable in the treatment of chronic ulcerative colitis.

One hesitates to be too dogmatic in suggesting that the problem is solved; it is not solved—there are still many, unexplained questions that present themselves. For instance, the wide variations that are obtained in the daily levels of penicillin in the stool or the blood, the failure to account for a good percentage of penicillin intake in the combined estimates in the urine, blood and stool and the wide range in the sensitivities of the various strains of intestinal organisms to penicillin administered orally are still unanswered.

Yet, considering the remarkable progress made in the field of antibiotics in the past two years, one remains hopeful. More work should be done and more standard criteria should be established.

CONCLUSIONS

1. Penicillin administered orally may be employed in chronic ulcerative colitis in doses from 100,000 to 300,000 units daily.
2. It is an aid in the management of chronic ulcerative colitis.
3. It is effective against some gram-positive organisms found in the stools of ulcerative colitis.
4. Penicillin levels were obtained in the urine, blood and stool.
5. Phthalylsulfathiazole and oral penicillin may be administered simultaneously to advantage.

CAUSES AND MANAGEMENT OF ANEMIA ASSOCIATED WITH CHRONIC ULCERATIVE COLITIS

H. MARVIN POLLARD, M.D.
MALCOLM BLOCK, M.D.
and
WILLIAM H. BACHRACH, M.D.
Ann Arbor, Mich.

The occurrence of anemia in association with chronic ulcerative colitis has been a common clinical observation for many years.[1] The exact incidence of anemia in this disease, however, has never been accurately studied, nor has there been a careful evaluation of the various factors which are important in its production. There have been a few general statements [1b, c] in regard to this anemia, but most of them have not been supported by either experimental or statistical data. For example, Haden [1c] states that in chronic ulcerative colitis there may be a microcytic hypochromic anemia, a macrocytic anemia or a normocytic one. The hypochromic, microcytic type is said to be the most common variety, being due to chronic hemorrhage and the consequent loss of iron. The macrocytic type is presumably due to a rapid passage of food material through the gastrointestinal tract or to some disturbance in the

Distribution of One Hundred and Nine Cases of Chronic Ulcerative Colitis by Age, Sex, and Extent of Anatomic Involvement

A.: Hematologic Picture of Chronic Ulcerative Colitis: Its Relation to Prognosis and Treatment, Am. J. M. Sc. **193**: 744-752 (June) 1937. (c) Haden, R. L.: Anemia in Relation to Diseases of the Colon, S. Clin. North America **19**: 1157-1162 (Oct.) 1939.

small intestine with a resultant deficiency in absorption of the erythrocyte-maturing factor. The depression of the bone marrow by associated toxemia and infection is said to be responsible for the occasional occurrence of normocytic anemia.

Because of the lack of material and information in regard to the occurrence of anemia with chronic ulcerative colitis, a study was made of 109 consecutive patients with this disease admitted to the University Hospital during the last five years. This material included patients of all ages and of both sexes, whose disease was of varying periods of duration and at all stages, in regard both to activity and to anatomic involvement of the gastrointestinal tract (the table). In an effort to standardize our data the cases were graded in regard to anatomic involvement as follows:

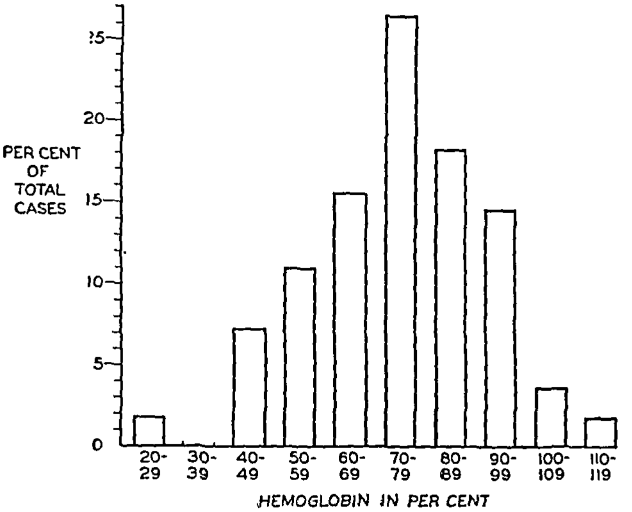

Chart 1.—Initial hemoglobin levels in 109 cases of chronic ulcerative colitis.

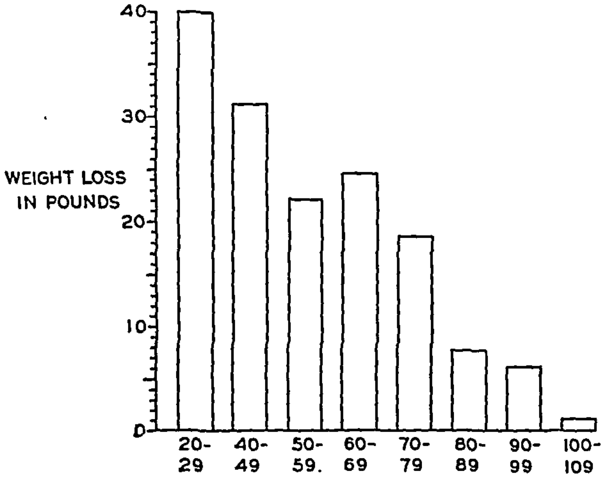

Chart 2.—Average loss of weight in relation to severity of anemia.

I. Involving rectum and sigmoid only
II. Involving rectum, sigmoid and descending colon
III. Involving rectum, sigmoid, descending and transverse colon
IV. Involving rectum and entire colon
V. Involving rectum, colon and terminal ileum

In regard to the evaluation of the activity of the disease, a case was considered to be in a period of remission if the temperature was normal, if the weight was increasing or was within 10 per cent of the value usual for the patient prior to the onset of his illness and if there was no diarrhea; that is, if there were no more than two or three stools daily and if these had some form.

In considering the anemia it was assumed that a hemoglobin value of 15.6 Gm. per hundred cubic centimeters of blood was 100 per cent, and if the hemoglobin was 80 per cent or more of this value the patient was not considered to have anemia. By means of this criterion, it was found that at the time of the original admission of the 109 patients to the University Hospital 71, or 65.1 per cent, had anemia. The distribution of the initial hemoglobin levels of all patients is shown in chart 1. An inspection of this chart reveals the hemoglobin values to lie generally on a curve which has the shape of a normal distribution curve, the peak, however, lying in the 70 to 79 per cent range, which is definitely in the anemia level. Of all patients with anemia, 58, or 81.6 per cent, had hypochromic, microcytic anemia and 13, or 18.4 per cent, had normocytic anemia. In this entire series there was no case of macrocytic anemia.

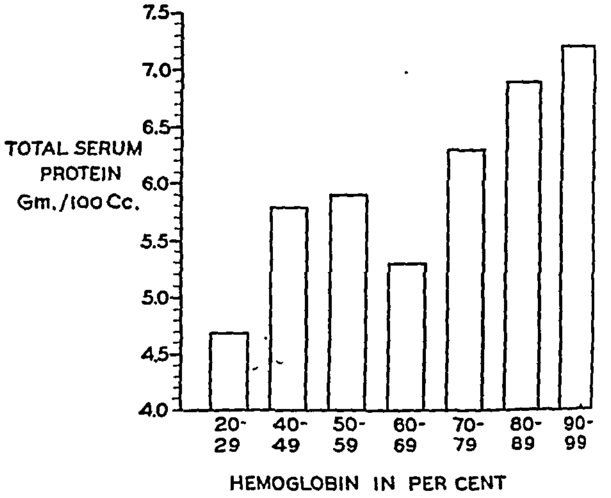

Chart 3.—Serum protein level in relation to anemia.

FACTORS POSSIBLY RESPONSIBLE FOR PRODUCTION OF ANEMIA

In attempting to determine those factors that may have been responsible for the production of the anemia the following items were considered:

1. The degree of iron deficiency produced by chronic hemorrhage, inadequate intake or absorption. In evaluating the last factor the occurrence of achlorhydria had to be considered.

2. The nutritional status of the patient, especially in regard to the adequacy of protein intake and absorption.

3. The influence of infection and toxemia on the ability of the body to utilize iron and protein in the production of hemoglobin.

1. *The Degree of Iron Deficiency.*—The degree of loss of blood was a difficult factor to evaluate because only 2 of the 109 patients failed to show loss of blood in the stools either grossly or on chemical examination. It is true that those patients with grossly bloody stools

or with a history of frank hemorrhage had severe anemia. On the contrary, in many cases in which there was severe anemia no greater degree of blood loss was revealed in the stools than in similar cases in which there was no anemia. Thus, from this point of view the occurrence of severe anemia in such cases appeared to be out of proportion to the amount of blood lost. It would seem, therefore, that loss of blood from the intestinal tract was a contributory factor in the production of anemia, and that it was not necessarily an essential one.

Our data on the occurrence of achlorhydria was inadequate to determine whether or not this was an important factor in producing impaired absorption of iron and a consequent anemia. In all of our cases in which a gastric analysis was done (15 cases) there was free hydrochloric acid in the fasting specimen. In 14 of these cases anemia was present with hemoglobin values below 70 per cent. In the other case the hemoglobin was 92 per cent. Mackie[2] has stated that 40 per cent (of 200 cases) of chronic ulcerative colitis exhibit achlorhydria, so that this factor may be more important than our data indicates

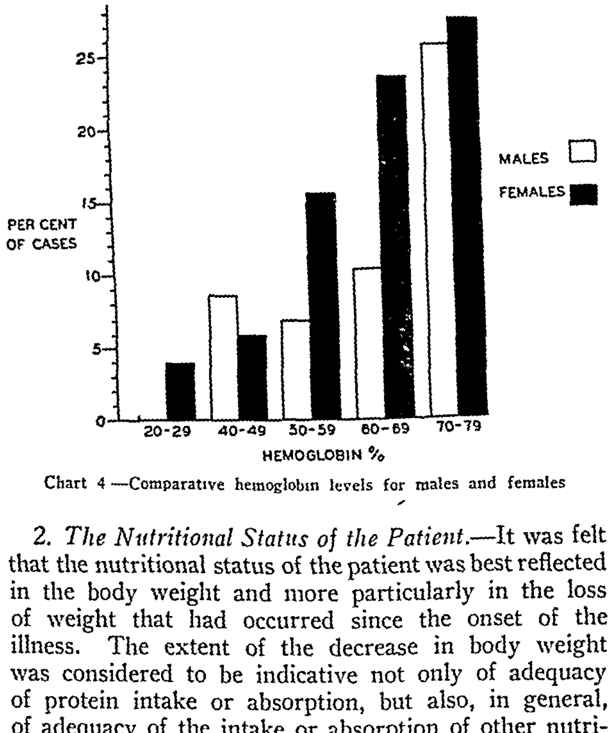

Chart 4—Comparative hemoglobin levels for males and females

2. *The Nutritional Status of the Patient.*—It was felt that the nutritional status of the patient was best reflected in the body weight and more particularly in the loss of weight that had occurred since the onset of the illness. The extent of the decrease in body weight was considered to be indicative not only of adequacy of protein intake or absorption, but also, in general, of adequacy of the intake or absorption of other nutritive factors that may be essential for formation of hemoglobin. Confirmation of this point of view was supplied by the frequent occurrence in those patients with severe loss of weight or other evidences of malnutrition such as glossitis, cheilosis and hyperkeratotic changes in the skin. In addition, the occurrence of a negative nitrogen balance, as well as deficiency in other essential nutritive elements, has been previously reported.[3] Elsom and his co-workers[4] have indicated that this disturbance of nitrogen balance may be related to an associated dysfunction of the small intestine.

Our data in correlating the degree of weight loss to the degree of anemia is shown in chart 2. It can be seen that there is almost a direct relationship between the degree of weight loss and the hemoglobin level. The relation of poor nutrition to the production of anemia has long been well established. Of interest in this respect is the absence of any case of macrocytic anemia in our series. Previous investigations[5] indicate that macrocytic anemia is more closely related to disease of the small intestine or gastric disease with consequent interference in the absorption of the erythrocyte-maturing factor rather than with disease of the large bowel as occurs in chronic ulcerative colitis. Besides, some of our cases of normocytic anemia may actually have been macrocytic ones, but so modified by iron deficiency as to give the morphologic picture of normocytic anemia.

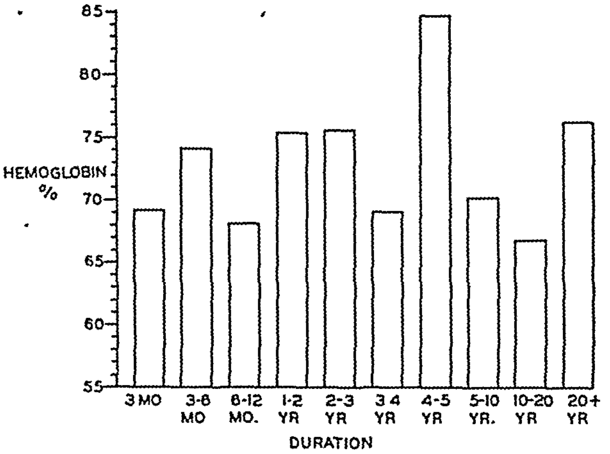

Chart 5—Relation of duration of disease and severity of anemia.

The level of the serum proteins was also considered as indicative of the protein-nutritional status of the patient. Total serum proteins were not determined in all cases, but in the 30 cases in which they were determined there was a close correlation between the severity of the anemia and the degree of deficiency of serum protein (chart 3). This evaluation in conjunction with that of the general nutritional status of the patient seems to indicate that an inadequate supply

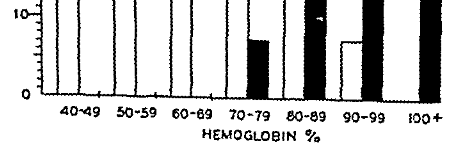

Chart 6—Comparative hemoglobin levels during remissions and exacerbations

of nutrients, particularly protein, to the patient with chronic ulcerative colitis is an important factor in the production of the associated anemia. Whether this lack of nutriment is due to an inadequate ingestion or inadequate absorption cannot be determined from our data, but it certainly does appear to be related to the incidence of anemia.

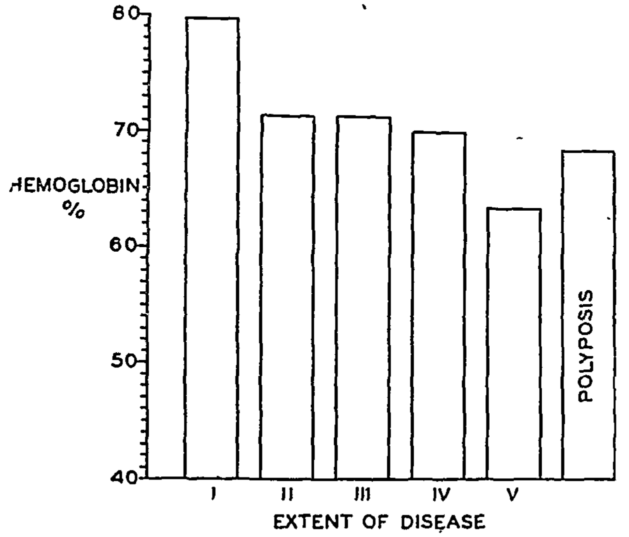

Chart 7.—Severity of anemia in relation to degree of anatomic involvement.

3. *Relation of Infection and Toxemia to Anemia.*—Anemia associated with infection and toxemia has been studied by Wintrobe,[6] and he has postulated that such an anemia is due to an inability of the body to utilize both the iron and protein in the formation of hemoglobin. We attempted to correlate the occurrence of anemia in our cases with the presence of infection and toxemia. An elevated temperature and leukocytosis were used as indexes of the presence or absence of toxemia. Of those cases with anemia there was an elevated temperature and leukocytosis in 53.2 per cent. This figure contrasts with the occurrence of fever and leukocytosis in only 18.4 per cent of those cases without anemia. This figure is significant enough to indicate that toxemia associated with chronic ulcerative colitis seems to be a factor in causing the anemia. In the cases of normocytic anemia this factor appears to be particularly important in that in 10 of the 13 cases of normocytic anemia there was a severe degree of toxemia, as indicated by high temperatures ranging up to 104 F.

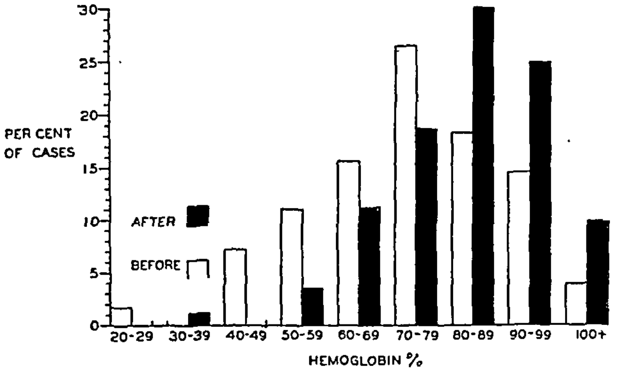

Chart 8.—Comparative hemoglobin values before and after treatment.

4. *Other Factors Playing a Possible Role in Production of Anemia.*—Under this heading an attempt was made to evaluate less specific items. For example, it was found that in females there tended to be a greater incidence of severe anemia than in males (chart 4). This observation is to be anticipated in view of the greater requirement in females[7] associated with menstruation and pregnancy, so that any factor tending to produce anemia would be reflected more severely in females. This factor was of particular interest in 2 of our cases in which the onset of the illness occurred during pregnancy and in both instances was associated with a rather severe hypochromic anemia.

The duration of the disease seemed to bear no direct relationship to either the occurrence or severity of anemia (chart 5). This seemed more closely related to the occurrence of exacerbations of the disease (chart 6). There is clearly an increase both in incidence and severity of anemia during exacerbations as contrasted with remissions. Likewise, the severity of the anemia seems to be directly related to the anatomic extent of the disease (chart 7).

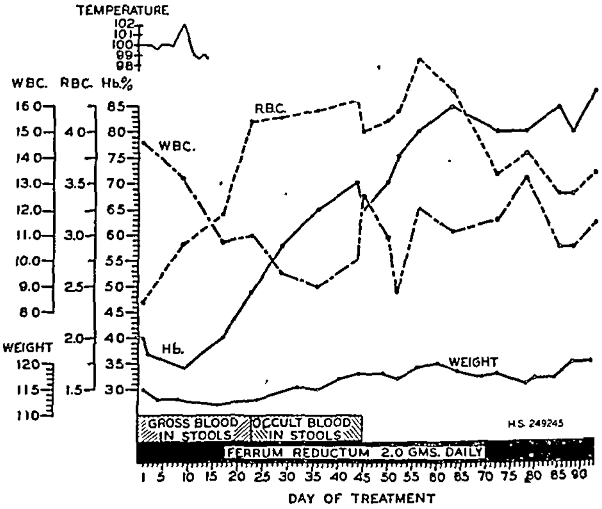

Chart 9.—Hypochromic anemia. Response to iron administered orally.

TREATMENT

It was of interest to evaluate grossly the effects of all treatment in all cases on the hemoglobin level. In chart 8 are the results of such an evaluation. The final hemoglobin levels after treatment was completed (patient discharged, failed to return or died) are contrasted with the initial values at admission. Here it can be seen that general incidence of anemia has decreased markedly, and in those cases in which anemia was still present its severity was generally less. Here the peak of hemoglobin values is 80 to 89 per cent as contrasted with 70 to 79 per cent prior to therapy.

In general, the treatment of the anemia was closely associated with the treatment of the disease. The material available for the treatment of the anemia included all materials used for the treatment of any anemia and consisted of iron, blood transfusions, a nutritionally adequate diet high in protein and the erythrocyte-maturing factors as exemplified by liver extract. Likewise, the therapy of the anemia depends on the morphologic type present from which the specific deficiency is ascertained. Thus, a hypochromic anemia is essentially an iron deficiency anemia, and its therapy is primarily the supplying of adequate iron. Because many factors seemed often responsible for the production of the anemia, however, it was often necessary to deviate from the general principles in therapy. For example, in managing a case of severe hypochromic anemia it was occasionally necessary to supply blood transfusions in addition to iron because severe prolonged gastrointestinal hemorrhage endangered the patient's life by producing a low blood pressure.

[7] Heath, C. W.: Iron in Nutrition: Requirements for Iron, J. A. M. A. **120**: 366-370 (Oct.) 1942.

Chart 9 illustrates an example of a hypochromic anemia. The toxemia was minimal in this instance as indicated by the only moderate transient fever and leukocytosis. The response to iron as indicated by the rising hemoglobin was not certainly adequate until the chronic loss of blood had decreased. It is of interest to note that the hemoglobin certainly did not fall, but rose slightly with the administration of iron even during the period when there was gross blood in the stools.

Chart 10 is another example of a hypochromic anemia. Here again the toxemia was minimal. However, there was the nutritional factor, of some importance in this instance as indicated by the low body weight. It is of interest that the anemia remained approximately stationary in spite of the administration of iron until the nutritional status improved as indicated by increase in body weight. At this stage the hemoglobin levels returned to normal promptly.

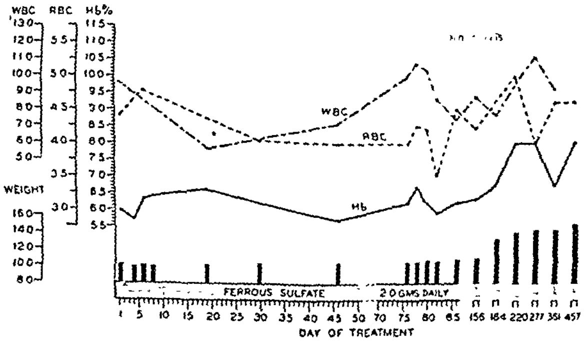

Chart 10.—Hypochromic anemia. Response of blood picture to iron and improvement of nutritional status.

In the cases of normocytic anemia the basic therapeutic indication is the use of transfusions. The use of such treatment is a temporary measure only to tide the patient over until the factors (such as toxemia) which are producing the anemia are overcome. This is well illustrated in chart 11. In this particular case it was possible to raise the hemoglobin by use of transfusions. This elevation of hemoglobin was transient and did not persist at a high level until the toxemia had cleared and there was a concomitant gain in weight. Chart 12 also indicates the ability to elevate the hemoglobin by use of transfusions even in the face of a severe toxemia.

The use of liver extract or other erythrocyte-maturing factors is indicated only in the presence of a macrocytic anemia. The use of crude liver extract parenterally may be indicated to supply other nutritive factors, but cannot be expected to have a specific hemopoietic value in either hypochromic or normocytic anemia. It is possible that in some instances of normocytic anemia there was an actual macrocytic anemia present, but so modified by loss of blood that the morphologic picture of a normocytic anemia resulted. In such instances liver extract would be of value, and its use is worthy of trial in cases in which the anemia does not respond adequately to iron and transfusions.

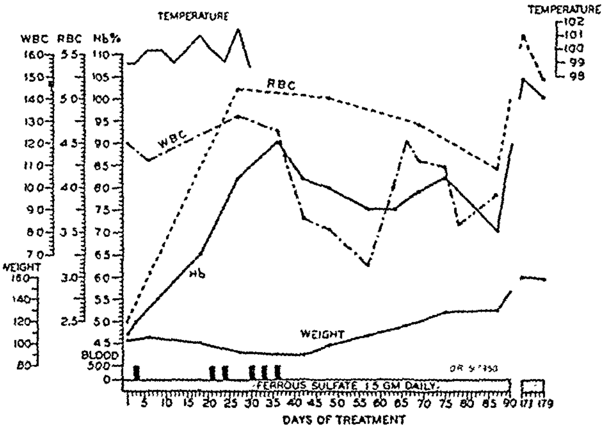

Chart 11.—Normocytic anemia. Effect of transfusions on anemia and improvement of nutritional status.

SUMMARY

One hundred and nine cases of chronic ulcerative colitis were studied in regard to the incidence of associated anemia. In 71 (65.1 per cent) of these cases anemia was present at the time of the original hospital admission. In 58 of the total of 71 there was a hypochromic microcytic anemia, while in 13 cases normocytic anemia was present. No cases of macrocytic anemia occurred in the series.

Many factors contribute to the causation of the anemia: (1) the degree of iron deficiency produced by chronic hemorrhage and inadequate intake or absorption; (2) the nutritional status of the patient as indicated by the degree of weight loss, evidence of avitaminosis and the level of the serum-protein; (3) the degree of toxemia and infection; (4) the anatomic extent of the disease; (5) the occurrence of exacerbations of the disease as contrasted with remissions, and (6) the sex of the patient, the anemia being more common and more severe in females.

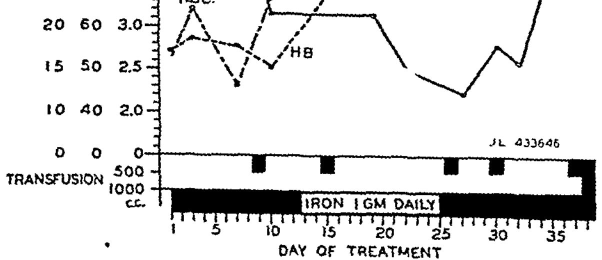

Chart 12.—Normocytic anemia. Influence of transfusions on hemoglobin level.

Treatment of the anemia follows the main principles laid down for the treatment of anemias in general. 1. Hypochromic anemias respond to iron given orally, but occasionally transfusions may be temporarily necessary because of low blood pressure. 2. Normocytic anemias respond temporarily to transfusions, but a sustained cure of the anemia is dependent on the cure of the toxemia, infection and malnutrition that produce the anemia. 3. Macrocytic anemia, if such might occur, should respond to injections of liver extract, as well as folic acid.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CROHN, GARLOCK AND YARNIS, DR. STREICHER AND DRS. POLLARD, BLOCK AND BACHRACH

DR. J. A. BARGEN, Rochester, Minn.: My remarks will concern Dr. Crohn's presentation on regional colitis. We are in general agreement concerning the nature and treatment of regional or segmental colitis. It may be best to consider it a disease entity. It does not seem the same as, or part of, the condition which we generally think of as regional enteritis. We have recently reviewed a series of 140 cases of regional colitis, and, interestingly, the largest number of our series occurred in the transverse part of the colon. A positive diagnosis is dependent on the roentgenologic manifestations. Medical treatment has value in the control of this trouble and does result in rather marked change in the bowel in a fair percentage of cases. Sulfathalidine has been of considerable help in treating these patients. Even when operation is contemplated the importance of the preoperative treatment cannot be overrated. We feel that resection in this group of cases, if operation is to be done, is the treatment of choice, and not just a short-circuiting operation. I should like to ask Dr. Crohn if he has an explanation of the thought offered by his group that with ileitis short-circuiting operations are satisfactory, whereas in this type of disease resection seems to be better.

DR. THEODORE L. ALTHAUSEN, San Francisco: Dr. Streicher should be commended for setting up such a thorough study of the effects of orally administered penicillin in patients with chronic ulcerative colitis. His studies on the bacterial response in the stools are uniform and convincing for the period of two weeks during which they were followed bacteriologically. One wishes that they were followed over more prolonged periods of time because in our experience the bacterial counts following an initial marked drop after the administration of sulfathalidine often go up almost to the original levels after two to four weeks, in spite of continued administration of this drug. Such a phenomenon might also be expected from our knowledge about the development of penicillin-fast and sulfonamide drug-fast bacterial strains in other diseases. The author's finding that the addition of sulfathalidine decreases the sensitivity of staphylococci and streptococci to penicillin is of interest. The reported levels of penicillin in the stools are surprisingly high. I should like to ask whether penicillin was administered to his patients in a single daily dose or in divided doses. The general clinical results of Dr. Streicher appear to be favorable. However, considerable caution until further confirmation is advisable in view of the initially favorable reports with the use of all kinds of antibacterial agents in the past which were later followed by a considerable scaling down of therapeutic claims, if not by total disappointment. I am inclined to be somewhat skeptical about the ultimate therapeutic results with any antibacterial agent in idiopathic ulcerative colitis because to my mind bacterial invasion in this disease is a secondary phenomenon which follows a primary breakdown of defenses in the colon, the cause of which, in most cases, remains unknown. My skepticism is reinforced by Dr. Streicher's non-committal remarks about the sigmoidoscopic appearance of the colonic mucosa of his patients after a year of treatment. It seems that a really successful remedy should have shown a distinct improvement in this respect. However, I am eager for really effective additions to our therapeutic armamentarium in ulcerative colitis and sincerely hope that Dr. Streicher's results may be not only confirmed but extended. I should like to ask Dr. Streicher whether he ever observed allergic sensitization to penicillin in his patients, because conditions for such sensitization are ideal in the ulcerated colon.

DR. EVERETT D. KIEFER, Boston: Dr. Pollard and Dr. Block are to be commended for choosing an important subject and for their able analysis of the problem. Our experience agrees with theirs, in that anemia is a common feature of ulcerative colitis and is of the hypochronic, microcytic type. As Dr. Pollard pointed out, the function of the bone marrow may be depressed in ulcerative colitis and unable to compensate for loss of blood due to the toxic effect of chronic infection, poor absorption of iron and food protein. There is evidence that the liver also suffers in this disease, which probably plays a part in some of the anemias. I believe that we are in agreement that the outstanding cause of anemia is the persistent hemorrhage into the colon. The pathologic changes in the mucosa are characteristically favorable for bleeding. The mucosa is congested, extremely friable and often ulcerated down to good-sized vessels. The exudate from the bowel includes important quantities of plasma proteins as well as hemoglobin. One might expect that the chronic diarrhea would tend to produce a vitamin K deficiency, and actually the prothrombin time is found reduced in some, but by no means all, cases. Other vitamin deficiencies are common; particularly the lack of vitamin C absorption also may increase the bleeding tendency through increase fragility of the capillaries. Secondary purpura is a rare complication, apparently produced in severely toxic cases or associated with drug idiosyncrasies and allergic reactions to foods. Bleeding in ulcerative colitis sometimes amounts to exsanguinating hemorrhages. In a group of 430 cases of ulcerative colitis, gross hemorrhage occurred in 12 cases, resulting in death in 3 cases and contributing to the death of a fourth patient. In 7 of the 12 cases, the gross hemorrhage appeared after an ileostomy was done. The treatment we have used for this complication is multiple transfusions, parenteral injections of vitamins, including vitamin K, opium and sedation. Several of these patients had from fifteen to twenty-five transfusions. We have felt that surgical intervention in the presence of acute hemorrhage is absolutely and definitely unwise, and have made no attempts to remove the bleeding area surgically. We have tried the instillation into the distal ileostomy loop of topical thrombin solution, with unconvincing success. In most of the cases, if one is persistent in giving repeated transfusions, the bleeding eventually stops.

DR. ALBERT H. ROWE, Oakland, California: During the last eight years we have accumulated evidence that chronic ulcerative colitis is often due to food and at times to pollen allergy which produces an eczematous-like reaction in the colon complicated in varying degrees with secondary infection, anemia, hypoproteinemia and avitaminosis. The edematous, erythematous and granular mucosa resembles the involved skin in atopic eczema due to food and pollen allergy. In cases of moderate or severe disease, vascular thromboses and necroses due to localized vascular allergy can explain the ulcerations. These may be intensified by secondary infection. Bleeding with consequent anemia can arise from the increased permeability of blood vessels, and free bleeding may arise from the necrotic vascular tissues resulting from localized vascular allergy. In 52 hospital cases and 18 office cases good or excellent results have arisen in 50 with the control of food allergy. Pollen allergy was the probable major cause in 3 cases and associated with food allergy in 5 others. Varying degrees of bleeding have been present in most of these patients, disappearing with the gradual control of the allergy. Transfusions were necessary in 26 and liver and vitamin K were given parenterally in many, but usually the bleeding stopped only after the allergy was controlled. Of the 15 patients failing to improve with allergic control 5 failed to cooperate, 1 gave no cooperation, 2 were controlled with sulfathalidine, 1 was controlled with sulfaquanidine, 3 had excellent results with ileostomy after allergic control failed, 2 died after ileostomy before diet trial had been used, and 2 died of perforation. The data on the slides which I will show illustrate the typical reduction in fever, diarrhea, cramping, and bleeding with the control of food and pollen allergy.

DR. RUSSELL S. BOLES, Philadelphia: It has always been difficult for me to accept the idea that any organism can be present in the bowel and active in causing ulceration or granulomatous formation without at the same time causing some disturbance in function. Of course, we find these organisms in the latent period. We have seen amebas in thoracic empyema, and in sections of the uterus, but at some time following their original invasion of the bowel, certainly, alterations of function must have been present. I want to ask Dr. Crohn about a particular case which I saw two weeks before I came out here, in which active acute inflammatory changes had occurred in the duodenum and jejunum and yet no disturbance of function of the bowel had occurred. This man was suspected of having a high lying, acutely inflamed appendix about which the surgeon and I both agreed. We operated on him, and he had what appeared to be regional duodenitis and jejunitis. Has Dr. Crohn seen cases of regional jejunitis in which at no time diarrhea had occurred?

DR. MARTIN S. KLECKNER, Allentown, Pa.: In the time allotted to me I did not have the opportunity to present certain slides which summarize the work done on this subject in private practice between 1940 and 1945. It has been my good fortune to observe that many other gastroenterologists, in addition to those I mentioned, together with the proctologists have done extensive work on chronic nonspecific ulcerative colitis. If you will observe the statistics on the slides, you will note that malignant growth was present in 9 per cent of the so-called "near" cases, whereas it was noted in only 4 per cent of the group listed as the "absolute." I may be criticized for using the terms "near" and "absolute," but I feel that an "absolute" division was necessary. Classification according to history obtained resulted in groups A, B, C and D. A careful interpretation of this slide will reveal interesting statistics. Seventy-two per cent were cured and improved. Further study of this slide reveals some interesting statistics on operation mortality and cure. I need not remind you that careful interpretation of the signs and symptoms in history taking leaves us in absolute accord, as far as the details of these cases are concerned. Furthermore, every certified proctologist invariably sees and studies pathologic conditions of the colon, and the progress of each case can only be followed by the complete and careful cooperation of both pathologic and roentgenologic laboratories. *In all these cases I insist on the double contrast* barium-air enema, but I do experience trouble in getting roentgenologists to give these patients sufficient time to go through with this procedure. The medical phase is summarized by rest, diet and the various therapies listed previously. On slide A-4 other drug therapy is presented. The occasional purge, the use of fullers' earth coupled with bismuth, the use of atropine alone or combined with codeine, the administration of calcium compounds and the careful use of iron with liver extract (which may increase the movement of the bowels and must then be discontinued if taken by mouth) together with replacement of vitamins, particularly the use of vitamin K by mouth or menadione bisulfite (hypodermically) and the administration of amino acids by mouth or intravenously when given with dextrose solution, has proved most helpful at times. I have used instillations of sulfathiazole and bismuth subgallate powder via the sigmoidoscope in the form of insufflations when the lesions are particularly bad around the rectosigmoidal area. In the last slide I have summarized the surgical phase, which does not always meet with the approval of the patient. However, I shall continue to urge surgical intervention whenever I feel that it is indicated.

DR. BURRILL B. CROHN, New York: There is something very satisfactory about the treatment and ultimate prognosis of segmental colitis. The outlook in universal colitis is always dubious, because of the constant tendency to recurrences. In the segmental type of case, patients either do well under conservative medical treatment or are operated on. Those that survive the 16 per cent operative mortality do well thereafter. The only exceptions are the 3 cases in which eventually the rectum became involved. Dr. Boles's question about the segmental form of jejunitis is interesting, though there is no common factor between these two diseases. Purely segmental forms of jejunitis do occur and are easily resectable with satisfactory results. Two striking cases were published in *Gastroenterology* **1**:347, 1943. Dr. Boles's query in regard to diarrhea is also interesting. It is essential to remember that segmental colitis, ileitis and jejunitis may occur without diarrhea, though such an occurrence is unusually rare.

DR. MICHAEL H. STREICHER, Chicago: I have three questions here. One is as to the dosage given. We gave three doses daily equally divided, about an hour or an hour and a half after meals; 100,000 units at each dose. The second question is about the proctoscopic aspect; I apparently did not make it clear enough. The entire problem was studied for one year. We had 45 patients to study and therefore did not have time to study all these cases proctoscopically. The third question is about the allergic phenomenon. We did have 1 patient react severely in the skin, with a severe rash, after administration of 50,000 units of penicillin on the third or fourth day, and from there on the rash lasted two weeks. Intravenous medication was given, and finally the patient did respond fairly well to additional doses of penicillin.

DR. H. MARVIN POLLARD, Ann Arbor, Mich.: As Dr. Kiefer mentioned, there is no doubt that some of the patients with chronic ulcerative colitis have some definite damage to the liver. This is probably on the basis of infection, as well as disturbed absorption from the small intestine, resulting in the decrease of the total serum proteins, a reversal of the albumin-globulin ratio and the production of a macrocytic anemia. The blood picture may be confused some in the presence of loss of blood from the colon, which produces a microcytic form of anemia rather than macrocytic. We have not included in this report our studies on increased capillary fragility in ulcerative colitis, but we have some information which suggests that this condition may be improved by the administration of rutin. In answer to the statement regarding transfusions, we have been reluctant to advise transfusions for our patients unless they are in a critical condition, with toxemia and active loss of blood from the lower bowel. Occasionally we have encountered a reaction to transfusion which has counterbalanced any beneficial effects which might have been obtained from the transfusion. As Dr. Bargen mentioned, we likewise have encountered difficulty occasionally in the administration of iron. This is unusual, however, in our experience. The preparation which we employ is that of enteric-coated ferrous sulfate, 5 or 10 grains (325 to 650 mg.) three times a day. The enteric-coated product has been found to be absorbed satisfactorily, and it is a helpful adjunct in the management of the microcytic anemia in these cases. In cooperation with our allergists, we have attempted to evaluate the role of food and pollen allergy in the management of these patients with chronic ulcerative colitis. Our enthusiasm has fluctuated considerably on this point and at the moment we are not finding many instances in which a specific food or pollen is playing a consistently significant role. It must be admitted that occasionally a patient will have an increase in the number of stools with some specific item of food. Whether this is a mechanical or allergic problem I am not yet convinced. Furthermore, what seems to be the offending food on one occasion frequently bears no relation to an exacerbation of the diarrhea some weeks or months later.

Veterans.—The Veterans Administration reports that as of March 3 about 5,000,000 veterans had applied for education and training under the G. I. bill. More than 3,500 veterans from World War I were carried on Veterans Administration rolls as amputees (loss of hands or feet or both). The number of Civil War veterans drawing pension from the Veterans Administration as of Jan. 31, 1947 was 116.

ANDROGEN THERAPY IN PROSTATIC DISEASE

FRANKLIN FARMAN, M D
WHITTIER, CALIF

The theory that benign hyperplasia of the prostate gland is the result of hormonal imbalance is supported by much experimental and clinical observation The fact that benign hypertrophy does not develop except in the presence of a functioning testis is the strongest evidence yet offered, according to Moore[1] that the disease is an endocrinologic dystrophy It is also well established that the testes are the main center of androgenic activity and exert a powerful influence on the development and function of the entire genital organs, for without the natural male hormone (testosterone) atrophy, hypogonadism, eunuchoidism and degrees thereof result There is no record of prostatic obstruction ever developing in a true eunuch, although Young[2] and others have performed prostatectomy on men previously castrated in early life Barron and Huggins[3] consider that removal of testicular androgens by excision causes atrophy of the prostate gland and cessation of secretion and it has been further demonstrated by Huggins and Stevens[4] that the prostatic epithelium at least is under control of the testicles

The exact histogenesis of benign hypertrophy is not known, but the fact that the nodulation of early hyperplasia occurs only in the lateral and middle lobes, the ambisexual part of the prostate, and that nodulation usually begins after the age of 40, with a corresponding decline of urinary androgens which are biochemically active points to endocrine influence On the other hand nodular hyperplasia never occurs in the posterior lobe which is the true prostate of the male, yet the latter commonly is the seat of primary carcinoma and as such is subject to endocrine influence The relationship between the testes and carcinoma of the prostate has been clearly demonstrated both by Huggins[5] through bilateral orchiectomy and by Munger[6] through direct radiation of the testes, thereby removing the main source of androgenic stimulation to cancerous growth This paper will not discuss the use of androgens in prostatic cancer, except to point out that injections of testosterone propionate may aggravate rather than relieve symptoms and may activate metastatic growth with corresponding increase in serum acid phosphatase levels (Huggins and Hodges)[5a]

Many therapeutic methods have been tried toward control of benign prostatic enlargement Castration was performed by White[7] in 1895, with 87 per cent of the patients reporting improvement Deming, Jenkins and van Wagener[8] found no change in the structure of benign hyperplasia thirty days after castration, yet Huggins and Stevens[4] (1940) have clearly shown that atrophy of prostatic epithelium will take place ninety days after bilateral orchiectomy and that recession in the size of the prostate will occur with improvement in the urinary stream The Steinach I operation (vasectomy) and the Steinach II (bilateral ligature of the efferent ducts of the testes) are attempts at control of benign enlargement of the prostate through increased production of the male hormone, but, according to Jacobs,[9] without much success

The modern conception of hormonal control was advanced by McGee[10] in *1927* with the extraction of an active androgenic substance from bull testes Since 1935, when Laqueur[11] first isolated true primary testosterone, synthetic androgens have been widely used the first were produced from cholesterol by Ruzicka[1]

Surgical excision of the prostate and transurethral resection of hyperplastic overgrowth give relief of certain urinary symptoms, but according to Moore[1] and others the basis for the disease remains; that is, the cause of hyperplasia is not removed by the operative procedure The not infrequent recurrence or regrowth (Tandler and Zuckerkandl,[13] Kretschmer,[14] Thomson Walker[15] and others) of prostatic tissue, especially after resection, is one proof of this Besides its surgical relief the need of an endocrine approach to the problem of all prostatic disease, in a manner that may be compared to the use of thiouracil in thyroid surgery, is becoming more apparent

Whether or not modification of androgenic activity by medical or surgical measures will restore hormonal balance (androgen-estrogen relationship) and retard development of benign nodular hyperplasia must await further experimental and clinical proof It is the opinion of Moore and McLellan,[16] Heckel,[17] Draper and others[18] *that the administration of testosterone propionate alone* does not alter the histologic structure of fully developed benign hypertrophy. Nevertheless the widespread use of androgens today indicates the potency of certain physiologic properties possessed by the steroid hormones Among these are vasodilation, increased muscular tonus and nitrogen storage The property of vasodilation has been made use of in the relief of angina due to coronary heart disease, and the muscular stimulus of testosterone has led to its use in increasing the

emptying power of the bladder. Testosterone propionate also seems to exhibit a general anabolic effect, aiding nitrogen retention and nutritional gain. Kenyon[19] has made use of this principle in the treatment of convalescent patients.

SUMMARY OF CASES

This analysis is based on the use of androgen therapy in 141 cases of prostatism. The cases are divided into four groups as follows:

I. *Chronic Prostatitis.*—Fifty-two patients with chronic prostatitis were given supplementary androgen therapy in amounts averaging 200 mg. of testosterone propionate besides the usual local treatment. Approximately one third gave a history of previous gonorrheal infection. In the 25 to 40 age group the duration of treatment was not shortened, averaging eight weeks, and no appreciable alteration in the course of the disease was noted. Normal androgenic function is the rule in the younger group, and the prostatitis seen is of the acute inflammatory type due to bacterial invasion, which responds satisfactorily to local therapeutic measures and chemosepsis.

However, in the older group aged 40 to 55 years, androgen therapy may well be used to advantage as an adjunct to commonly accepted measures: digital massage, local heat, urinary antiseptics, the antibiotics, urethral instrumentation and medication as indicated. In 37 cases of chronic recurrent prostatitis in men past 40 years of age, the response to combined androgenic and local treatment has been more rapid, more permanent and more productive of clinical cures (86 per cent) than formerly, that is the prostatic secretions became nearly free of inflammatory products and the size and consistency of the prostate receded to near normal with relief of symptoms. In some patients symptoms of the now recognized "male climacteric," such as nervousness, sleeplessness, poor appetite and lassitude, were distinctly benefited.

To respond to androgens a prostate must have a potential active secretory capacity, as androgens apparently stimulate normal epithelial cells to secrete either directly or through the mechanism of vasodilatation and increased blood flow. The fibrous prostate does not respond, and usually symptoms are not relieved. If a patient does not respond then one should check further to ascertain the reason. Cystoscopic examination, and tests for residual infection in the upper part of urinary tract should be made, and other remote causes should be sought. Frequently unsuspected fibromuscular hyperplasia, fibrosis of the neck of the bladder, diverticula, prostatic calculi and the like will be found which requires operative correction rather than continued local treatment.

Case 1.—*Androgen Therapy in Acute Prostatitis with Abscess.*—J. D. H., a man aged 46, had acute urinary retention due to acute prostatitis with abscess formation. The condition subsided after the initial placement of an indwelling catheter followed later by digital massage and administration of 310 mg. of testosterone propionate intramuscularly over a two month period. From an acutely swollen, firm, resistant, abscessed gland, the prostate returned to average size and medium consistency. Urination became free and effortless; the prostatic secretions became copious and almost free of cellular elements.

In my experience this was one of the most graphic examples of the possible value of androgen therapy in acute prostatitis with abscess, obviating the necessity of surgical drainage either by perineal section or transurethral methods (resection). Further trial of this plan of treatment is recommended.

II. *Benign Hyperplasia Not Submitted to Surgical Measures.*—A group of 40 patients with benign hyperplasia have been treated entirely without surgical intervention. The average age was 62 years. The outstanding symptoms were increasing frequency of urination, nocturia, urgency, slowness, suprapubic or perineal discomfort and frequently impotence. The rectal and cystoscopic findings usually pointed to grade 1 to 3 glandular enlargement. Residual amounts of urine generally ran under 60 cc. Obstruction to the passage of urine and insufficiency of the bladder wall had not developed. Approximately half the patients showed definite associated prostatitis, as determined by study of the prostatic fluid. This is not the prostatitis engrafted on a normal gland by bacterial invasion but is a type of presenile hypertrophy with resultant inflammatory infiltration.

The principal method of treatment consisted in biweekly intergluteal injections of testosterone propionate supplemented when necessary with methyl testosterone tablets by mouth so as to bring the average weekly dose up to 50 mg. of available hormone. The absorbable rate by mouth is about 1 to 4 as compared with intramuscular injections. The total amount given ranged from 100 to 1,500 mg., with an average of 300 mg. given in any one period. Usually additional treatment was given; that is, prostatic massage, irrigation of the bladder and urinary antiseptics were given as indicated, and occasionally a sound was passed if the urinary stream remained restricted.

The clinical effect in this group of patients with benign hyperplasia has been consistently good, otherwise the case was transferred to the operative list. Positive symptomatic and objective proof of improvement was recorded by patients' statements, tests for residual urine and microscopic examination of prostatic secretions. The statement most consistently made by the patient was "I feel better." The force and ease of the urinary stream increased with reduction of residual urine, frequency (especially nocturia) decreased and pressure symptoms of urgency or perineal discomfort were relieved. Impotence is one symptom generally not improved. The most rapid improvement occurred in those whose disease was associated with definite degrees of prostatitis, for as the inflammatory infiltration subsided the symptoms improved and the size of the prostate receded, due not to any actual reduction of hyperplastic nodulation but rather to a disappearance of edema and round cell invasion.

Case 2.—*Reduction of Residual Urine.*—R. W. J., a man aged 51, a salesman, came in complaining of slowness of urination, frequency, nocturia and suprapubic discomfort. Cystoscopic and rectal examination disclosed a typical grade 2 hyperplasia of the prostate with residual urine of 110 cc. Intensive treatment was given during the first two months, since which time monthly observations have been carried out. He received a total of 425 mg. of testosterone propionate by intergluteal injection. After one year's time the residual urine remains at 20 cc., the nocturia has decreased to one time and the urinary stream is free. In his case it is not anticipated that resection will not be indicated eventually, but for the time being he is clinically well.

---

[19] Kenyon, A. T.: Problems in the Endocrine Aspects of Convalescence, paper read before the meeting of the California Medical Association, May 7, 1946.

Case 3.—*Slow Development of Benign Hypertrophy.*—F. H. F., a man aged 69, is a wholesale paper merchant. In 1936 he had a typical grade 2 benign hypertrophy associated with some degree of prostatitis; that is, the expressed prostatic fluid contained 2 plus pus cells in clumps and 20 cc. of residual urine was recorded. Today, after ten years, the rectal findings are typical of a grade 4 smooth, rounded benign hyperplasia. The prostatic secretions have practically ceased, and those expressed contain few scattered pus cells About one and a half years ago periodic androgen therapy was started because of increased urinary frequency, nocturia and dribbling with residual urine of 60 cc. A total of 600 mg. of testosterone propionate has been given by intergluteal injection. The amount of residual urine has decreased to 20 cc., the urinary stream has improved and general tonus has been maintained. Total prostatectomy or resection has been repeatedly advised, but this patient chooses to continue a "business as usual" regimen. My fears of an acute stage of urinary retention have not come about, which is the only symptom that influences many men to undergo surgical intervention.

The surprising thing about such patients is the fact that they can be carried along for indefinite periods of time without apparent increase in their symptoms or increase in the size of the gland. Frequency, slowness and nocturia in themselves, though sleep-disturbing, are not necessarily an indication for immediate surgical intervention. However, continued chronic vesical retention with infection should be relieved surgically. This and similar cases convinces me that it is not necessary to advise immediate operation in well selected patients, and that average good health may be maintained for long periods by treatment and observation as outlined. The patients who do the best under androgen therapy are those who fall into the age group 50 to 65 years and have uncomplicated grade 1 to 2 benign adenomatous hyperplasia associated with some degree of chronic prostatitis.

III. *Benign Hyperplasia of Prostate Treated Preoperatively with Androgens.*—In 14 cases of benign hyperplasia the patients were treated preoperatively with testosterone propionate and then submitted to operative removal of their obstruction. Few cases are included in this group because a patient who requires operative intervention usually is not subjected first to androgen therapy. The average age of patients in this group was 65. The symptoms were much the same as in group II: urinary frequency, nocturia, urgency, slowness and occasionally dribbling. Suprapubic and perineal discomfort were not prominent. This is a symptom more of prostatitis than of hyperplasia in my experience. Residual amounts of urine were not great—from 30 to 70 cc. on the average. In 1 patient acute urinary retention developed, and in 1 case there was chronic retention (250 cc. residual). Both were subjected to preliminary cystotomy. Both the rectal and the cystoscopic finding as a rule pointed more to fibromuscular than to glandular hyperplasia. Androgen therapy did not relieve patients in this group; in fact, in a few instances residual amounts of urine became greater and the symptoms increased. Temporary improvement was recorded in some patients, possibly due to auxiliary treatment consisting of urethral dilation (sounds), bladder irrigations and prostatic massage.

In view of the negative clinical response to androgen therapy in amounts varying from 125 to 1,500 mg. of testosterone propionate given by intergluteal injection, patients in this group were submitted to operative treatment, 12 by transurethral resection and 2 by suprapubic prostatectomy. A review of the histologic sections showed predominantly fibromuscular hyperplasia, less adenomatous hyperplasia and consistently little round cell invasion. This observation supports the conclusion that androgenic (testosterone) treatment will reduce inflammatory infiltration of the prostate either in one undergoing hyperplasia or in chronic prostatitis. Keller and Hull[20] noted a similar effect.

IV. *Postoperative Use of Androgen Therapy.*—Androgen was administered to 35 patients subsequent to transurethral resection and suprapubic prostatectomy. Intramuscular injections of testosterone propionate in amounts ranging from 100 to 300 mg. were given during the immediate convalescent periods. When indicated vesical lavage and urethral dilation were performed and urinary antiseptics were administered. The trauma of resection, the atony of the bladder wall after spinal anesthesia and the general low metabolic state of the patient are factors to be considered. I have found that supplementary androgen therapy even in small amounts may bring about a quick response, relieving such postoperative sequelae as frequency, burning, pyuria or hemorrhagic urine, urethral irritation and spasm of the bladder.

In many cases of late recurrence of symptoms it is unnecessary to perform a second resection, as treatment with androgens and local measures will give the patient prompt relief. The effect is more noticeable in those who have had previous bilateral vasectomy, possibly due to reactivation of the interstitial cells of the testes. In 6 cases reported in this series such treatment was given with prompt relief of symptoms. Chronic infection of prostatic tissue not removed by resection is one cause of recurring symptoms; another is regrowth of hyperplastic nodules, which lends support to the endocrine theory that the basis of benign hypertrophy is not removed by operative intervention. It is understandable that seldom does transurethral resection remove all prostatic nodules, no matter how well performed, and for this reason the rationale of hormonal therapy during convalescence and the follow-up period should be investigated further as a means of preventing future prostatism.

In 3 cases of delayed healing of the suprapubic wound following second stage prostatectomy in which there was pronounced atonicity of the bladder (residual urine of 1,000 cc. or more on admission) testosterone propionate injections did relieve the mental depression, improve the general tonus and start the patient on nutritional gain. The need for hormonal therapy in such debilitated patients during their immediate convalescence is suggested.

CONCLUSIONS

1. Androgen therapy is not a substitute for surgical relief of benign prostatic obstruction with insufficiency of the bladder wall.

2. The male hormone, testosterone, should seldom be administered before the age of 40, which is the age at which nodular hyperplasia may begin, except in selected cases of testicular absence or deficiency.

---

[20] Keller, W. F., and Hull, W. M.: Histopathological Changes in the Prostate Following Testosterone Propionate Therapy, Urol. & Cutan. Rev. 44: 18, 1940.

3. Androgen therapy is most useful in cases of early benign hyperplasia in which there is associated prostatitis.

4. The postoperative aspects of hormonal therapy after prostatic surgery should be carefully considered.

ABSTRACT OF DISCUSSION

Dr. Willard Thompson, Chicago: There are two types of carcinoma of the prostate, one dependent for its growth on stimulation by androgens and the other not dependent on this factor. The type that depends for its growth on androgen stimulation is the one that is relieved by bilateral orchiectomy or by functional castration with diethylstilbestrol. It is interesting to cite a related experience which has just come into the foreground. Dr. Adair, in a panel discussion in the joint session on Internal Medicine and Experimental Medicine, reported that at the Memorial Hospital in New York they have produced corresponding changes in carcinoma of the breast by administration of testosterone in doses of 100 mg. three times a week for a period of eight to ten weeks. He reported that in such cases the roentgenologic evidence of metastases may disappear, just as Huggins reported that metastases in bone in patients with carcinoma of the prostate may disappear following removal of the testes. Improvement in carcinoma of the breast has been reported as a result of removal of the ovary. My colleague Dr. Heckel has made a careful study of this problem and feels that administration of the male sex hormone is not of much value in benign prostatic hypertrophy. The development of the prostate depends on stimulation by androgens. Since that is the case, it is difficult to see why the administration of male sex hormone would be of much value. Some observers feel that improvement may result from some effect on the tone of the muscle of the bladder. I am glad to hear that Dr. Farman also feels that androgen therapy is not of much value. Dr. Farman's observations on chronic prostatitis are of considerable interest. His suggestion of giving the male sex hormone during the period of convalescence from operations on the prostate is an interesting one, and it may well be that the improvement in the general condition of the patient as a result of administration of testosterone propionate may be an important factor in the convalescence of the patient.

Dr Roy Henline, New York: Dr. Farman has taken a proper attitude concerning the value of androgens administered in prostatic hyperplasia. Symptomatic benefits are frequently obtained in prostatic infections, yet prostatic smears often fail to demonstrate comparable improvement. This symptomatic relief may be due to the improvement in the muscle tone of the bladder. In a similar way, as mentioned by Dr. Farman, there is some evidence indicative of the beneficial effects of androgen therapy on coronary disease Thus the effect of androgen in the human body deserves further investigation and clarification. It has recently been brought to my attention by Dr. Elmer Belt of Los Angeles that androgens administered in large doses are beneficial in treatment of urinary suppression. He cited several patients with complete anuria who began secreting urine after the administration of androgens. It is administered as testosterone propionate in peanut oil or as testosterone pellets The indiscriminate use of androgen therapy, because of its relationship to cancer, should be discouraged.

Dr. Monroe Wolf, New Orleans: May I ask how that preparation was given, whether in oil or solution?

Dr. Roy Henline, New York: It was given intramuscularly and also as testosterone pellets.

Dr. Wolf: Was that the methyl salt or propionate?

Dr. Henline: The propionate was used in the intramuscular administration.

ACTINOMYCOSIS OF THE FACE AND NECK

JOHN H. LAMB, M.D.
EVERETT S. LAIN, M.D.
and
PHYLLIS E. JONES, M.D.
Oklahoma City

Cutaneous actinomycosis may appear near any body cavity but is seen most frequently about the mouth. All the cases about to be discussed were so located. Cervicofacial actinomycosis may be primary or secondary. The primary form is comparatively rare, and as 15 of our cases were of the secondary type, the present discussion will be limited for the most part to that form of the disease.

INCIDENCE

Formerly regarded as a regional disease, a wider knowledge of bacteriology has made the members of the medical profession alert to detect actinomycosis in nearly every portion of the globe—"wherever there is a microscope and a laboratory," as Zachary Cope has put it. Cope,[1] writing in 1939, noted that for the previous six years there had been just 60 deaths from actinomycosis in Great Britain. He does not give the total number of cases reported. In the United States in the two decades from 1920 to 1940 data have been obtained on 839 cases of all types of clinical actinomycosis, particularly in regard to their distribution throughout the different states. The greatest number of cases were seen in the Mississippi valley and the Northwest Central states. Minnesota reported 163, Illinois 101, Iowa 56, Michigan 91 and Ohio 24. Of the Northeastern states, New York led with 54 cases; Pennsylvania had 36 and Connecticut 23. In the Southeastern states Virginia's 28 cases led Georgia's 16, Florida's 14, Tennessee's 8 and Kentucky's 2. Of the Western Plains states, Missouri gave a total of 48 cases, Kansas 24, Oklahoma 21, Colorado 19, North Dakota 16, Nebraska 10 and Texas 8. In the far west California was estimated at 51 and Montana 18. The states not mentioned reported but 2 or 3 cases or none at all. Probably many cases in which the patients do not manifest all the clinical symptoms are entirely overlooked, and it may be well that those states and countries reporting the largest number of cases are those in which recognition averages higher. To quote Cope again, "The more carefully the fungus is sought, the more often it is found."

ETIOLOGY

Identification of the Organism.—The identity of the organism responsible for actinomycosis in man has been a controversial question. Bostroem[2] in 1890 isolated an aerobic actinomyces, which he believed to be the causative factor in submaxillary lesions. Later investigators demonstrated an anaerobic pleomorphic organism, which was at first a threadlike fungus, later segmenting into a bacillus; and this common parasite[3]

Read before the Section on Dermatology and Syphilology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

Because of lack of space this article is abbreviated in The Journal by omission of portions of the text The complete article will appear in the authors' reprints

[2] Bostroem, E Untersuchungen uber die Aktinomykose des Menschen, Beitr. z. path Anat. 9: 1-240, 1890.

[3] We are in agreement with Rosebury's suggestion that the word parasite be used to mean an obligate parasite for Actinomyces bovis when it is found in a nonpathogenic state. "Saprophytic" will be used only in reference to the soil group (Streptomyces) of actinomyces. Rosebury, Theodor: The Parasitic Actinomycetes and Other Filamentous Microorganisms of the Mouth, Bacteriological Review 8: 189 224 (Sept) 1944.

in carious teeth and normal tonsils afterward was proved to be the causative organism in perimandibular actinomycosis. Others observed it in the root canals of the teeth. It was the opinion of Axhausen[4] that infection by the fungus depended on a previously existing or coexistent invasion of pyogenic organisms, the invaded tissue being thereby altered until the parasitic fungus became a pathogenic foreign agent. In such a lesion the granules may be many times removed by radical surgical intervention without their true nature being recognized unless a histologic study is made. New areas of induration and abscess formation may come into existence if the actinomycetes penetrate the borders of a local focus after its surgical extirpation. The majority of observers have for a long time considered the anaerobic, non-spore-bearing actinomyces as the commonest etiologic agent of human actinomycosis, and there has been a trend in the clinical literature for cutaneous lesions due to the aerobic actinomyces to be termed nocardiosis.[5] Guy[6] expressed the opinion that too much was included under the title "actinomycosis." He felt that actinomycosis of the skin is a definite clinical entity in which the ray fungus is always present and that this picture differed materially from that presented by tissues invaded by the non-spore-bearing aerobe.

TABLE 1.—*Nomenclature and Classification of Actinomycetales*

1. Vegetative mycelium fragments into bacillary or coccoid elements.

    Family: Actinomycetaceae, Buchanan

    A. Anaerobic, parasitic, not acid-fast: Actinomyces, Harz (bovis)

    B. Aerobic, partially acid-fast or non-acid-fast; multiplication by fragmentation of the mycelium; lack of aerial hyphae-forming spores: Nocardia, Trevisan

2. Vegetative mycelium not fragmenting into bacillary or coccoid elements

    Family: Streptomycetaceae, Waksman and Henrici

    A. Multiplication by conidia in chains from aerial hyphae (common soil actinomyces): Streptomyces, Waksman and Henrici

    B. Multiplication by single terminal spores on short sporophores: Micromonospora, Orskov

After Waksman and Henrici[7]

Waksman and Henrici[7] have offered the best suggestion for nomenclature and classification of the Actinomycetales to date (table 1).

Methods of Culture.—The common soil streptomyces are easily cultured for the most part on simple mediums, including potato sliced up and sterilized in a tube, but numerous factors must be considered when culturing nocardia and actinomycetes from human or animal tissues. The medium must be enriched with acetic fluid or whole blood; it must be either neutral or of a slightly alkaline p_H, and its temperature must be consistently maintained at 37 C.

In our case 1 all the blood agar plates incubated at this temperature were positive for the aerobic actinomycete, but all other mediums—Sabouraud's agar, veal infusion, broth or agar—on which the original fluid was inoculated showed no growth even when the temperature was carefully maintained throughout at 37 C. Not until the third or fourth subculture could we obtain growth on any medium save that first mentioned. Domingo and his co-workers[8] by careful bacteriologic methods were likewise able to get a positive growth of Actinomyces madurae in one of five tubes inoculated with material from a patient with cervicofacial actinomycosis.

Straw Chewing Theory.—With the acceptance by nearly all investigators during the past twenty years of Actinomyces bovis as the etiologic agent, the legend that actinomycosis of the head and neck is connected with chewing straws must be abandoned.[9] There is no evidence that this organism is capable of producing spores or otherwise maintaining growth on vegetable matter. Many strains fail to live past the fourth subculture, even when grown on the most carefully prepared medium with precise temperature consistently maintained.

There is, however, a remote possibility that in the granulating form the fungus is so protected from unfavorable outside influences as to be able to maintain a semianaerobic state, thus making it able to infect straws or other foreign particles. Because the disease affects men far oftener than it does women and, in this country at least, men are more likely to be in prolonged contact with farm animals than are women—and possibly more prone to chew straws—this legend has become more credible. Only a few of the affected persons gave a history of having chewed straws, so it has probably been overstressed in consideration of etiologic factors. Yet the high incidence of cervicofacial actinomycosis in the so-called dairy states is too suggestive to be entirely ignored.

In general animal inoculation experiments have been inconclusive. The acid-fast strain Actinomyces phenotaleron, isolated by Gammel,[10] is pathogenic for guinea pigs if inoculation is made in the lungs. But both aerobic and anaerobic types of actinomyces, if non-acid-fast, have proved almost universally negative in animal inoculation. It would seem that some aerobic strains such as that isolated in 1 of our cases are not highly pathogenic for man, since this patient had carried the infection for fifteen years.

Probably many cases diagnosed as simple pyogenic periodontitis are mild infections with the anaerobic A. bovis strain. Axhausen was surprised to find as high as 28 per cent of patients with these mild early cases showing granules when he excised tissue from the affected area for microscopic examination. In his opinion many cases are overlooked.

Theory of Allergic Sensitization.—That infection results not from a single exposure to the parasite but from repeated absorption which leads eventually to allergic sensitization is the theory propounded by Mathieson and his colleagues.[11] The progressive disease we call actinomycosis would be the result of such sensitization. Experiments with animals indicate that both vaccination and other methods of introducing infection, if frequently repeated, may induce allergy. Rabbits were more easily sensitized than guinea pigs, and the allergic reaction was more pronounced with the highly virulent Actinomyces asteroides than with the less virulent Actinomyces gypsoides. Oft repeated vaccination leads to desensitization, and there is some evidence that immunization accompanies this reaction. But there is

no evidence that sensitization to the acid-fast actinomycetes was accompanied by a like reaction to commercial tuberculin of human type or that any protection against tuberculosis was afforded by such sensitization or immunization. Certain experiments along this line, however, have suggested that allergic sensitization may be a factor in the etiology of actinomycosis.

PRIMARY CUTANEOUS ACTINOMYCOSIS

Primary cutaneous actinomycosis is a designation which should be restricted to those cutaneous cases in which the infection does not spread from a neighboring mucous membrane or arise from a systemic infection. Instances of this form are probably less infrequent than figures usually indicate (1 to 2 per cent), but the diagnosis is usually difficult unless biopsies are taken and serial studies are carried out with both aerobic and anaeroblic cultures. All species of actinomycetes have been accused as etiologic agents in primary actinomycosis. In our only case of primary actinomycosis colonies of nocardia were cultured. It is the fifth case of nocardiosis cutis to be reported in American literature, and a more detailed report than has appeared previously in the literature [12] is here given.

History.—A man aged 61, a farmer, had a pustular lesion at the hair line of the neck sixteen years before examination. Twelve years before, several large nodules developed in the supraclavicular region, which were diagnosed as cancer and treated with corrosive pastes by quacks Five months before examination similar nodules appeared in the left supraclavicular region. On examination by us, three large, bluish red, fluctuant tumors were seen in the left supraclavicular region; in the right fossa were several ulcerated areas, 1 to 2 cm. in diameter, with grayish red bases and sloping edges—apparently the site of previous sloughing due to the action of zinc chloride paste. Radiographic examination of the chest showed an infiltration at the base of the left lung—a condition thought to be compatible with fungous infiltration due to actinomycetes. The diagnosis was nocardiosis; treatment consisted of sulfanilamide compounds given by mouth and roentgen therapy to the infected areas. The patient succumbed to coronary thrombosis while he was under treatment; permission for autopsy was refused

Laboratory Observation.—A moist smear of fluid obtained by sterile puncture from a nonulcerated tumor in the left supraclavicular fossa showed no granules or fungi; stained smears showed no acid-fast or other bacteria. After two days' incubation at 37 C. (99.5 F.) aerobically, four cultures on blood agar plates showed minute, tenacious colonies of fungi resembling nocardia. The organism was non-acid-fast and gram-positive. Glucose agar shake tubes and Sabouraud's agar slants inoculated at the same time with fluid from the tumor showed no growth at the end of a month.

Two week old cultures of the aerobic nocardia on blood agar showed gradually enlarging colonies of a brownish mucoid growth; later snow-white aerial mycelium formed, and the typical musty odor characteristic of nocardia was noted.

The second and third subcultures failed to grow on any medium except blood agar at 37 C., but after two months' subculture the fungus grew on other mediums at room temperature. The mycelium was nonseptate and the aerial mycelium short, but true branching of the mycelium was noted. Study of mycelium from various mediums failed to show any sporogenous hyphae or conidia.

Cultural Characteristics.—Gelatin was liquefied; minute colonies were cultured on potato but they were never luxuriant, and no pigment was formed. There was no acid or coagulation on litmus milk and no utilization of starch On blood agar the blood pigment was slowly destroyed, with a wide area of hemolysis about the colonies. In beef infusion whitish puff balls, delicate and fuzzy, floated at different levels, becoming firmly attached to the walls of the tube. Of the sugars—after four weeks' growth—sucrose, lactose, dextrose and maltose showed neither acid nor gas. The growth on Sabouraud's agar was scant and failed to show any pigment in the mediums.

General Conclusion.—The characteristics presented by this actinomycete seem in all ways similar to those of nocardia but not compatible with any recorded species. Therefore the name Nocardia hemolyticus is suggested.

Animal Inoculation.—One rabbit intravenously injected with 2 cc. of a rather heavy suspension of the organism, with simultaneous introduction into the pleural spaces, failed to manifest any elevation of temperature. At autopsy after three months the same rabbit showed nothing but a small encapsulated abscess in the lung at the site of intrathoracic injection. The abscess consisted of a small inflammatory area composed of lymphocytes. No granules were demonstrable. Growth of the organism from material from a second rabbit used for these injections was obtained after several months on culture mediums. More positive results might have followed the use of cultures nearer the original, before virulence was reduced or entirely lost.

PATHOLOGY: FORMATION OF GRANULES

Two theories have been advanced to account for the formation of clubs. One attributes to them a developmental part in the life cycle of the organism; the other regards them as a thickening of the sheaths enclosing the filaments as a protection against the effect of animal fluids. Bayne-Jones [13] has shown that to regard club formation as exclusively the result of interaction between organism and animal fluids is incorrect. He demonstrated that club formation may take place in simple glucose agar and glucose broth by Actinomyces hominis without the addition of serum or any other animal protein.

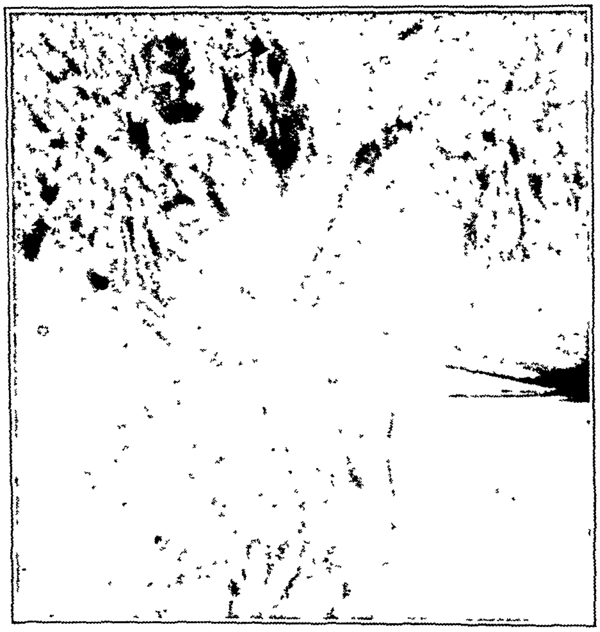

Fig. 1 (case 4).—Asteroid microcolonies of actinomycetes.

Not all species of pathogenic actinomycetes produce club-bearing granules, and clinically granules are not in evidence in all cases of actinomycosis. Emmons [14] has emphasized the mistake of assuming that because clubs are conspicuous in tissue invaded by one certain species of actinomycetes they are an essential feature of actinomycosis. Other infections produce granules as well. In botryomycosis of horses—in which the etiologic factor is a staphylococcus—clubs radiate from gram-positive masses of micrococci enclosed in a zoogleic substance. Granules with clubs are formed under certain conditions[15] by other organisms, such as Coccidiodes immitis and strains of Aspergillus, Sporotrichum and Monilia. This emphasizes the importance of crushing and staining all granules before examination so as to ascertain whether they are formed by bacteria or fungi. In our studies of many unstained smears, in all stages of the disease, there seemed to be a definite chronologic order of appearance of three distinct types of granules.

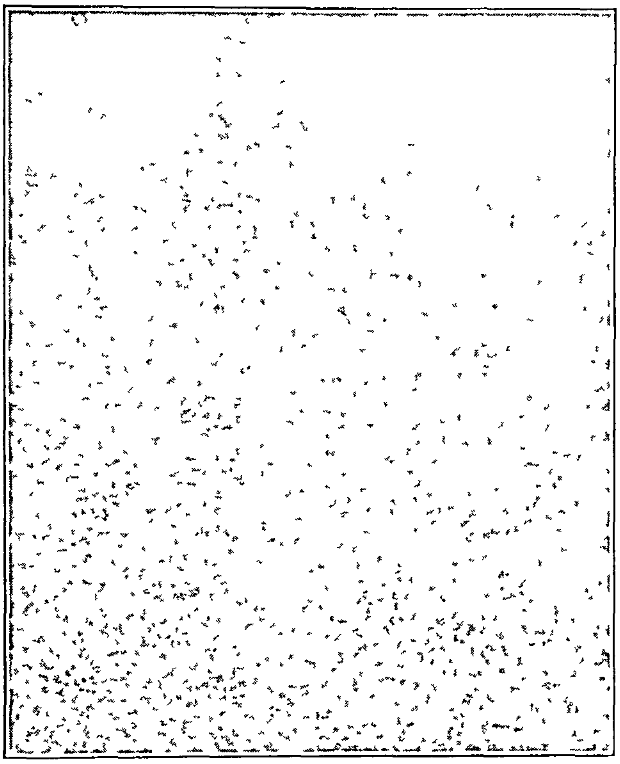

Fig 2 (case 3).—Matted filaments of actinomycetes in a soft granule

1. When a smear was made early in the disease, from fresh pus, organisms were seldom demonstrated, but in cases 4 and 12 microcolonies were in evidence (fig. 1), the actinomycetes being 20 to 25 microns in diameter. The arrangement they assume may best be described as an aster, or leptothrix-like form,[16] radially fixed about a small central axis. The separate filaments were the usual size of actinomycetes, located about 15 microns from the central pivot. In making the smear many of these short filaments were broken up into separate long rods; these were recovered only five or six days after treatment had been instituted and did not have the appearance of cholesterol crystals, in which all the radiations of the spicules are in one plane. The examiner was obliged to focus up and down in order to follow the filaments from the central axis to the tip. They were gram-positive.

In both cases 4 and 12 we were able to cultivate anaerobically, in dextrose agar shake tubes, an organism similar to that described as A. bovis. Later in the course of the disease typical sulfur granules appeared.

The careful pathologic study of Poiteau,[17] describing a similar evolution of the parasite in an early nodule in actinomycosis of the breast, contains the following description:

> Right in the center is the parasite, represented by mycelium undergoing evolution. The mycelian elements, mixed together in a very irregular way in the center, are regularly arranged at the periphery. The periphery portions of these filaments are arranged parallel to each other, and give the first indication of a tendency to peripheral radiation which characterizes the adult grains of the actinomycosis, only at this stage the clubs are not yet formed.

This is the earliest reference in the literature to microcolonies and represents a transition from the asteroid form to the second type of microcolony, the soft granule (fig. 2).

2. In this second type—the soft granule stage—we may see the effects of ten to twelve days of treatment, as we did in 4 of our cases. Emmons[14] recognized this early type of granule, having found it in actinomycotic meningitis, as well as in 2 cases of facial actinomycosis. The cultures were in all cases typical of A. bovis, but no clubs accompanied the granules. Henry[18] observed granules which yielded no clubs in a case of cerebrospinal meningitis caused by A. bovis

Such findings are probably not infrequent,[19] but their occurrence has not been sufficiently emphasized. The soft granules may be explained as a reaction to the environment provided by the host, or they may indicate either a recent infection or one in which the normal degree of resistance has not yet been established. Two of our patients when reexamined later in the course of the disease showed granules with clubs.

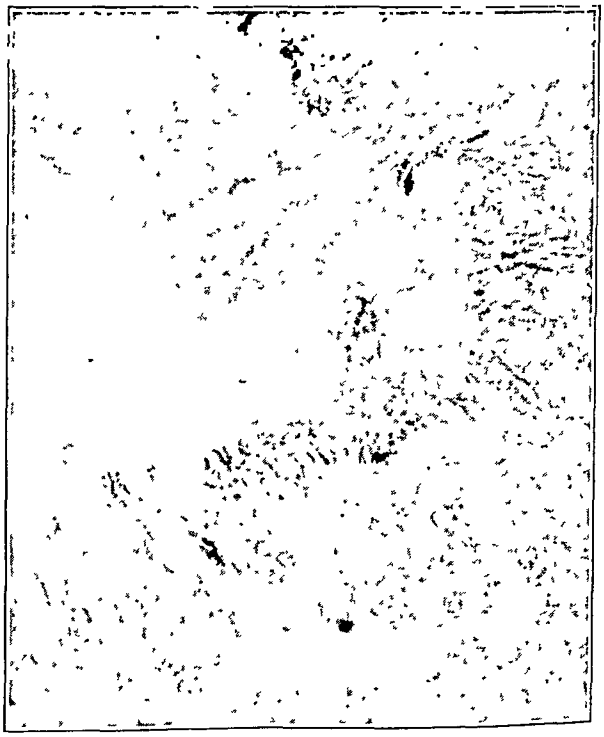

Fig. 3 (case 1).—Transitional type of granule with both clubs and penetrating hyphae.

[19] Conant, N. F., and others: Manual of Clinical Mycology, Philadelphia, W B. Saunders Company, 1944.

On microscopic examination the soft granule is found to consist of the matted filaments of actinomycetes—from six to ten bundles forming the granule. The filaments are disposed in whorls, under high power magnification presenting a design suggestive of a fingerprint. A definite "ray effect" is brought about in some areas by the arrangement of the filaments at right angles to a clearer area in the center

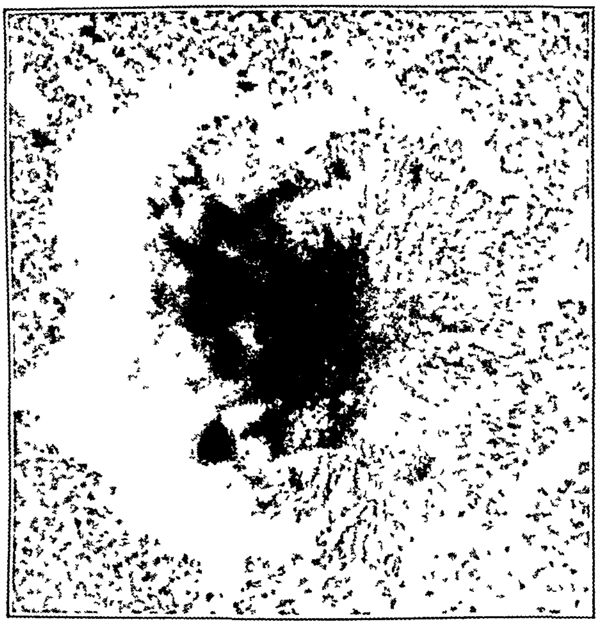

Fig 4 —The ray effect of the central area in which the mycelium penetrates through the peripheral arrangement of clubs (Gram's stain).

At the granule's periphery is seen loose mycelium, its size suggesting that of the actinomycete, and in several areas the mycelium may enlarge in an abortive attempt to form clubs or begin chlamydosporulation By allowing the pus to strain through fine gauze fresh soft granules may be recovered and immersed in isotonic solution of sodium chloride. When we studied such granules several layers of large, multinucleated giant cells were revealed about the granule. Each cell had three or four nuclei, and the entire cell was four to five times the size of a monocyte They were egg shaped with a granular material filling the cytoplasm They appeared actually to be macrophages trying to destroy the actinomycetic infiltration. This leads to the conclusion that as the immunity of the host to the actinomycete increases, the fungus makes some effort to survive its unfavorable environment In the early stages of the infection an excellent propagation site under anaerobic conditions is offered the organism in the dense, woody, fibrous edema with little vascularity, which the spread of the disease provides Treatment—such as roentgen radiation in sufficient dosage to produce an erythema—gives the tissues a higher oxygen potential, making living conditions much harder for the growing actinomycetes. It is probably at this stage that chlamydosporulation takes place. The spore provides itself with a chitinous covering as it enlarges, and the typical clubs are produced by an antigen-antibody interaction, much as the pneumococcus secretes its capsule. In case 1 (fig. 3) there was some pathologic evidence pointing toward an intermediary stage, represented by a granule composed both of clubs and penetrating hyphae. As this granule was photographed immediately after its recovery from the smear, the penetrating hyphae do not represent growth of the fungus after the material was secured.

3. The third type—the typical sulfur granule—we found so like that which has many times previously been described that little can be added concerning it.

The sulfur granule is composed of a dense reticulum of fibrils which takes the violet dye in sections stained by Gram's method. Around the periphery of the granule the ends of individual filaments may be seen projecting through the clubs, out into the surrounding infiltrate (fig. 4). Sections stained by Gram's method must be studied in twenty-four hours, since most preparations for permanent mounting tend to completely remove the gentian violet from the stained mycelium. This leaves an eosin-stained granule which shows the clubs and the central bacterial débris which has been so commonly and wrongly described as such in past reports. This central mycelium may be restained repeated times and each time shows up nicely but fails to retain the dye. Part or all of the periphery may be composed of radially arranged hyaline clubs. The clubs usually take the eosin stain with Gram's method. They are several times wider than the filaments whose ends they enclose, and the filaments can sometimes be traced within the structure of the club. Examined under the oil immersion lens, there is some suggestion of filamentous composition of the clubs (fig. 5), while some of the clubs appear to be septate. Dr. G. L Clark of Urbana, Ill., has generously placed at our disposal the results of studies made by him and his associates, with the aid of the electron microscope, on sulfur granules from our patients. His preliminary report is available at this time:

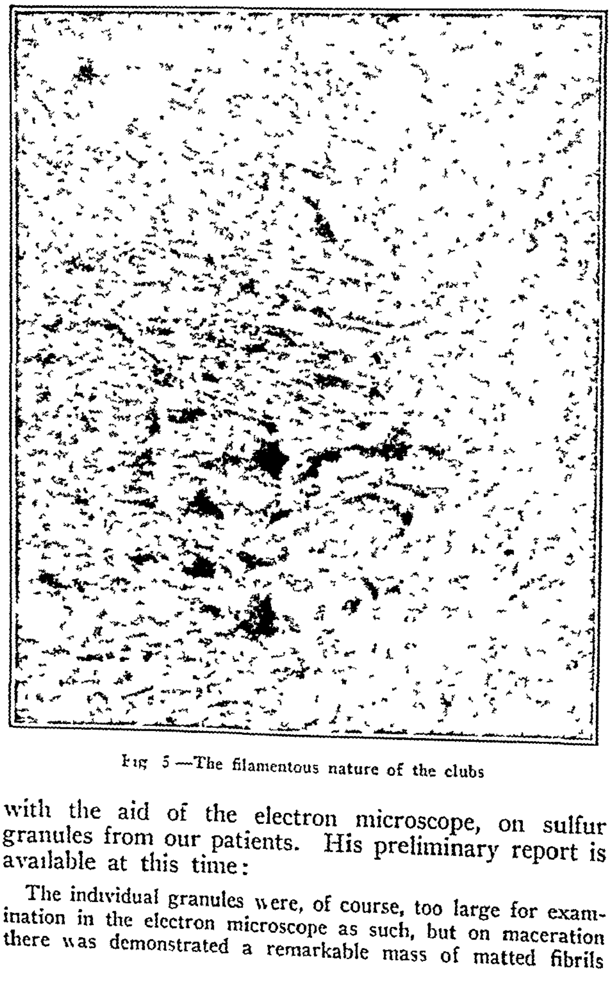

Fig 5 —The filamentous nature of the clubs

> The individual granules were, of course, too large for examination in the electron microscope as such, but on maceration there was demonstrated a remarkable mass of matted fibrils

(fig. 6) which seems to constitute the center of the granules, together with a variety of amorphous material in the interstices of the network and fragments of what appeared to be the concentric layers of membranes forming the shell of the granule. The mat of the fibrils is almost of molecular dimensions and corresponds closely with the nucleoprotein fibrils which are obtained from the chromatin of cells by the Claude technic. This fibril formation, therefore, seems to be a general morphologic feature even under these pathologic conditions.

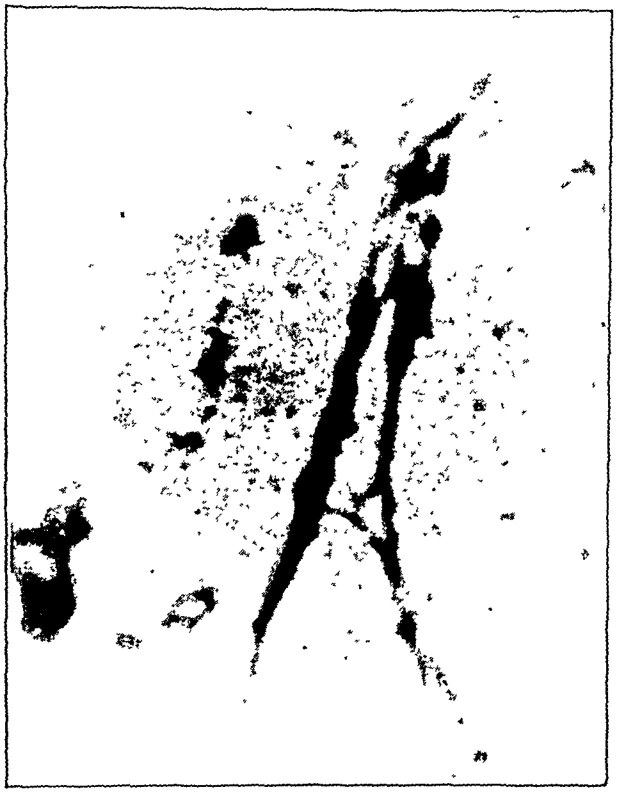

Fig 6.—Fibrils which constitute the center of the granules (slightly reduced electron photomicrograph, × 100,000)

CLINICAL MANIFESTATIONS

The onset of the disease in our experience has been insidious. The usual history is of chronic peridontitis *surrounding* a carious tooth or teeth (fig. 7), often going back for several years. During this time there may be swelling about the alveolar processes and even in the soft tissues, with more or less pain. There is alternate regression of the active process and recurrence with exacerbation. During the period of regression the fungus probably migrates through the root canal or through the gingival pockets directly to the bone and soft tissues, along with secondary bacterial contamination. Each recurrence reduces the resistance of the tissues to the parasitic invader. This is consistent with Axhausen's opinion, already cited, that the person becomes hypersensitive to the actinomycetes, the resulting actinomycosis being an allergic reaction, on the part of the host, to a common parasitic inhabitant of the mouth, teeth and tonsils. In most of our cases the acute stage of actinomycosis had been preceded by the removal of infected or pulpless teeth. Twenty-four to forty-eight hours after extraction of such a tooth there had been a slight rise of temperature, with edema and swelling of the soft tissues about the mandible. In subacute cases the lesion consisted of firm subcutaneous tumors of purplish hue, which gradually softened, ulcerated and broke down, leaving fistulous tracts.

The rapid, acute form of the disease spread gradually until all the soft tissues as far down as the clavicle were a solid wall of dense edema, with bluish red erythema. There was often a rise of temperature to 101 or 102 F., and the patient complained of such subjective symptoms as hoarseness, difficulty in swallowing or choking. Inspection usually showed a central necrosis in the area in which the infection originated, with little true pus but with a suppuration of a clear, straw-colored fluid. As sinuses formed secondary bacterial invasion increased, particularly that of staphylococci and streptococci. In some cases the disease proved extremely resistant to treatment and became chronic, but in most instances treatment greatly shortened the duration of the disease, and roentgen exposures greatly altered its course.

DIAGNOSIS

The salient points in the diagnosis of actinomycosis of the face and neck are:[20] (1) dark red discoloration of the skin ("slate blue" lesions); (2) projection of the lesion beyond the surrounding integument; (3) multiple nodules, with the formation of ridges and furrows in the creases of the skin of the neck; (4) distinct (boardlike) induration; (5) multiple sinuses, with both macroscopic and microscopic granules of actinomycetes in the pus; (6) history of chronic periodontitis followed by an acute exacerbation of the inflammation of the gum after extraction of an abscessed tooth, and (7) pain that if present is not severe; it is often absent entirely.

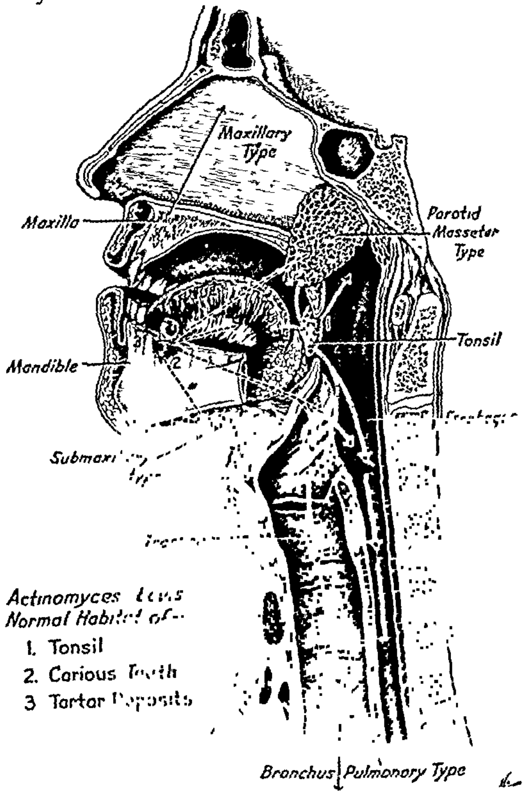

Fig. 7.—The possible routes of infection in the transition from a parasitic actinomycete to a pathogen.

Differential Diagnosis.—Tuberculous Gumma: Actinomycosis must be differentiated from tuberculous gumma. This may be difficult at first, but as caseation takes place the lesion fluctuates but is not indurated, and the dark red spots characteristic of actinomycotic

---

20. Monestié, F.: Actinomycosis of the Skin, Internat. Clin. 3:73-82, 1921.

infection are absent. A tuberculous gumma opens as a single sinus and is painless, without the boardlike hardness of actinomycosis. Tuberculous adenitis is a condition seen in early life, while actinomycosis may occur at any age. Search for Mycobacterium tuberculosis in the pus will aid in establishing the diagnosis.

Syphilitic Gumma: Syphilitic lesions are less indurated and clear up more promptly. There is usually a single circular opening with cleancut edges and a grayish or yellowish base. A history of syphilis or the presence of other characteristic syphilitic lesions, together with the results of the Wassermann test, will generally serve for differentiation.

Other Manifestations: Blastomycosis is annular and granulomatous, and cultures of the blastomycete will verify these findings. Budding, yeastlike cells will be found in the tissues. In lupus vulgaris the process is of long duration, tending to chronicity, with permanent scarring. The biopsy will show epitheloid cells and giant cells, typical of the tuberculoid structure, and no granules will be found. Periosteal sarcoma quickly affects the general health, with early cachexia, and biopsy will at once demonstrate malignant growth. In Hodgkin's disease and lymphosarcoma there will be no history of dental trauma, while other glandular areas will show the characteristic manifestations. In both these diseases there is likely to be loss of weight, cough and daily elevation of temperature. A branchial cyst may enlarge and become sufficiently inflamed to mimic the picture presented by actinomycosis. Deep aspiration with the needle may reveal a gelatinous fluid. Sometimes only surgical removal and biopsy will differentiate this cyst.

Metastasis: Metastasis from a cutaneous epithelioma appearing in the submaxillary region has occasionally simulated actinomycosis. Such lesions, however, are much more indurated and do not fluctuate, and there will be a history of removal or treatment of the primary lesions, with a scar at its site. Moreover, metastases from neoplasms do not have the bluish color characteristic of actinomycosis. Because of its location, cervical venereal lymphogranuloma may occasionally cause confusion but can be recognized if the Frei test is positive.

TREATMENT

Drug Therapy.—Sulfonamide Compounds: After Walker[21] (1938) suggested the use of sulfonamide compounds in the treatment of the anaerobic type of cervicofacial actinomycosis, we successfully employed this form of therapy in many of our cases. However, the treatment must be prolonged and the dosage adequate, using larger doses in the acute stages than in the subacute and chronic types of infection. In our most recent cases we have employed sulfadiazine by preference, but from 1939 onward all the sulfonamide drugs except sulfapyridine have given equal satisfaction. The dosage was as follows: Sulfadiazine 8 Gm. in the first twenty-four hours of the acute stage. Reduce to 6 Gm. per twenty-four hours for four to five days; then 4 Gm. for several weeks; then 2 to 3 Gm. daily for the following two months, if the patient tolerates the drug well.

Liver extract—10 units three times a week—is regularly prescribed during prolonged sulfonamide therapy. We believe the patient is less toxic, and we have had no cases of leukopenia or agranulocytosis as yet. We attribute this to the use of liver extract in conjunction with sulfonamide therapy.

Many actinomycosis infections are undoubtedly aborted by dentists who employ sulfonamide compounds before and after the extraction of pulpless and infected teeth.

Penicillin:[22] Herrell was apparently the first to employ penicillin in the treatment of actinomycosis, reporting 50 per cent of success in 1942. In a recent personal communication he suggests using a dosage much larger than that employed in his earlier work—as high as 1 million units daily for a ten day period, with three such courses to be given. A number of other workers (Lyons,[23] Florey and Florey[24] and Walker and Hamilton[25]) have reported their results in treating actinomycosis with penicillin. Lyons' results were generally good, at least temporary improvement occurring in 4 cases. The Floreys reported failure with 2 of their patients. Walker and Hamilton had success in 6 cases, in most of which treatment was carried on for six weeks or more. Their highest total dosage was 8,170,000 units. They considered surgical excision of the scar and underlying fibrous, or granulomatous, tissue essential for success with penicillin therapy.

We have used penicillin in 7 cases of cervicofacial actinomycosis. Three patients responded splendidly; the other 4 improved somewhat but did not do as well as on sulfadiazine therapy. The fourth patient received 2 million units of penicillin in all, the dosage being 25,000 units every three hours; during the administration of the drug five satellite lesions developed about the central nodule. In 1 case of actinomycotic osteomyelitis of the mandible, in which the soft tissues exhibited a sinus draining through the skin, cure was effected by a daily dosage of 300,000 or even as high as 400,000 units of penicillin, prolonged over two months.

Other Therapeutic Agents: Before 1939 we found the iodides valuable in certain instances. Thymol, gold salts and polyvalent vaccine, for which others have made strong claims, we have not so far tried.

Roentgen Therapy.—In 11 of our cases roentgen radiations in large doses were decidedly successful. The results in 5 other patients were not so fortunate. One patient refused to continue the treatment until the full dosage had been received; another had already had both radium and roentgen therapy under a mistaken diagnosis of carcinoma of the inner cheek; the third and fourth patients could not attend regularly enough to get the full dosage, and the fifth patient died while the treatment was in progress.

It has been our experience that many infections show no response to roentgen therapy in lessening the number of new lesions or retarding the progress of the disease until over one half of the total amount of radiation decided on has been given or a moderate erythema has appeared. The kilovoltage and total dosage have varied greatly from one to another of our cases, but every patient who pursued the course to the end received distinct benefit. Since the infiltration of the involved tissues rarely exceeds 3 to 4 cm., we have worked out the following technic: kilovoltage 120 to 140 is used with aluminum filtration of 4 or 6 mm., or with aluminum filtration of 1 mm. plus 0.25 mm. copper at a distance of 12 to 14 inches (30 to 36 cm.). A dosage of 150 r every other day is maintained until 1,500 to 2,200 r have been given.

A much higher dosage will be tolerated if the treatment is given only once or twice a week, and radiation therapy may be prolonged in this manner for as many as eight weeks. For the acute phases of actinomycosis the heavier filtration of 6 mm. aluminum or 0.25 mm. copper and 1 mm. aluminum was preferred, since the treatment could be given in a higher total dosage over a longer period of time, with less danger of the manifestation of remote roentgenologic sequelae when the original actinomycosis was entirely cured. The total roentgen dosage in each case is dependent on the size of field to which the treatment is administered.

Surgical Treatment.—Radical surgical removal of large areas of tissue in acute or subacute cases is definitely contraindicated. The recurrence of infection in the surgical scar is almost inevitable. This is only too well illustrated in our cases 12 and 14, wherein both patients had extensive local removal of tissue, soon followed by recurrence of the infiltration all about the scarred areas. Permanent cure was accomplished for both these patients by roentgen therapy.

In cases in which there is involvement of the mandible with sinus formation through the soft tissues to the cutaneous surface the infection must first be controlled by roentgen, sulfonamide and penicillin therapy, to be followed by excision of any sequestrums of residual osteomyelitis in the mandible. A pathologic fracture of the mandible calls for orthopedic treatment, while a sinus which fails to heal often requires intervention by the plastic surgeon.

BRIEF SUMMARY OF FIFTEEN CASES OF SECONDARY CERVICOFACIAL ACTINOMYCOSIS

Fifteen cases of cervicofacial actinomycosis (table 2) have been observed in the past eight years. Data from the case histories have been compiled in table 2. To summarize, the entire group of cases was in white patients—six women and nine men. The average age was 41.

TABLE 2.—*Summary of the Histories of Fifteen Cases of Cervicofacial Actinomycosis*

Case	Race	Sex	Age	Occupation	Location and Duration	Culture	Previous Removal of Tooth	Granules Found	Roentgen Rays and Iodides Used	Time to Cure	Roentgen Rays and Penicillin	Time to Cure	Roentgen Rays and Sulfanilamide	Time to Cure
1	W	♀	34	Wife of stockman	Inframandibular, 3 mos.	—	Yes	Sulfur	Yes	7 mos.	—	—	—	—
2	W	♀	41	Wife of truck driver	Inframandibular, 6 mos.	—	Yes	Sulfur	Yes	4 mos.	—	—	—	—
3	W	♂	34	Grocer and horse trader	Inframandibular, 2 mos.	+ A. bovis	Yes	Soft type	—	—	Yes, 2 mil. U.	Failure	Yes	6 wks.
4	W	♀	41	Music teacher	Inframandibular, 1 mo.	—	Yes	Asteroid and sulfur	—	—	—	—	Yes	2 mos.
5	W	♂	52	Grocer	Inframandibular, 3 wks.	—	Yes	Sulfur	—	—	—	—	Yes	2 mos.
6	W	♀	56	Housewife	Inframandibular, bone involvement, 3 yrs.	—	2 yrs before	Sulfur	—	—	Yes, 8 mil. U.	2 mos. cured	—	—
7	W	♀	61	Housewife	Inframandibular, bone involvement, 2 yrs.	—	No	Sulfur	Yes	Failure	Yes, 6 mil. U.	Failure	Sulfonamide reaction	—
8	W	♀	24	Housewife	Supramandibular, 2½ mos	—	Yes	Sulfur	—	—	Yes, 2.5 mil. U.	Failure	Yes	6 wks.
9	W	♂	45	Oilfield worker	Supramandibular, bone involvement, 10 mos.	—	No	None	Yes	1 recurrence, cured 2 mos.	—	—	—	—
10	W	♂	56	Farmer	Acute parotid masseter, 6 mos.	—	No	None	Yes	Cured 1 yr. with 2 recurrences	—	—	—	—
11	W	♂	36	School teacher	Acute parotid masseter, bone involvement; 4 yrs.	—	Yes	Soft granule	—	—	Yes, 3 mil. U.; with sequestrectomy	2 recurrences, cured in 1 yr.	—	—
12	W	♂	43	Cement finisher	Acute perimandibular, 6 mos	+ A. bovis	Yes	Asteroid	—	—	—	—	Yes	3 recurrences cured in 1 yr.
13	W	♂	35	Salesman	Acute perimandibular, 9 mos.	—	Yes	Sulfur	—	—	—	—	Yes	2 recurrences cured in 9 mos.
14	W	♂	24	Truck driver	Acute perimandibular, 6 mos.	—	Yes	Sulfur	—	—	—	—	Yes	2 mos.
15	W	♂	42	Farmer	Acute perimandibular, 4 mos.	—	Yes	—	—	—	Inadequate dosage of both roentgen rays and penicillin	Failure to date	—	—

The incidence of the infection seemed to bear little relationship to occupation. Only 2 patients were farmers. The occupations of the others are given in table 2.

The location of the disease varied; in 7 cases there was a fairly well demarcated area below the mandible in the submaxillary region. The exact location was about equally divided between the middle portion of the area between the angle of the jaw and the chin, the angle of the jaw and under the chin.

Two infections were located on the cheek above the mandible or supramandibular.

Two cases involved the parotid-masseter region and were of the acute type, with trismus of the muscles in this area—the mouth barely admitting one or two fingers.

Four of the cases were of the acute perimandibular type with swelling above the mandible and below, even extending down to the clavicle. In 1 of these cases there was extension of the lesion to the clavicle on both sides of the neck and around the left ear to the occiput at the midline.

The duration of the disease before the patients were examined by us ranged from two months to four years. A study of the cases shows that early diagnosis and treatment seems to offer a better prognosis for cure.

In 2 cases cultures grown anaerobically in glucose agar shake tubes showed the small, smooth, grayish white colonies of gram-positive pleomorphic bacilli identified as A. bovis.

Granules of various types have been found in 12 instances—in 3 cases the diagnosis was made on a clinical basis only.

The removal of one or more carious teeth preceded the infection in 11 cases and was the cause of a severe relapse in 2 cases. Nine patients suffered recurrences. Six had more than one recurrence.

The results of treatment have been gratifying. Four patients treated by roentgen radiation and iodide therapy were entirely cured. In 1 case treatment with iodides alone resulted in failure. Seven patients treated with the sulfonamide drugs and roentgen rays were cured. Of 5 patients treated with penicillin and roentgen rays, only 2 were cured. Thirteen of 15 patients were cured by various other methods. The time to produce a complete cure varied from one and a half months to four years. This was counting the time in remission between recurrences.

COMMENT

Actinomycosis of the face and neck, as seen in our experience, is a persistent, recurrent and disabling disease in the majority of cases—11 of 16—but has never been fatal, though 1 patient died of other cause while under treatment. Five patients had neither complications nor recurrence after the initial treatment. Seven factors probably operated in the recurrent cases:

1. The virulence of the organism.
2. Lowering of the patient's resistance by overwork, mental strain or undernourishment due to fear of artificial dentures or the poor condition of natural teeth, leading to improper mastication.
3. Further impairment of immunity-producing balance between actinomycetes and body fluids by release of new organisms into the tissues when another abscessed tooth was removed or the skin of the old involved areas was surgically excised.
4. Any kind of trauma to the affected region.
5. Involvement of the mandible overlooked during the original treatment period, so that it remained as a focus of recurrence.

Thoma[26] has stated that in central actinomycosis of the mandible, destruction of the bone may exist for a long time before symptoms appear; frequently it is by roentgen diagnosis that an osteitic defect is discovered which proves on operative intervention to be due to actinomycosis.

6. Failure to administer in adequate dosage the drugs which inhibit growth of the actinomycete—sulfadiazine and penicillin—giving them for the minimum rather than the maximum number of days.
7. Too intensive roentgen dosage for too short a period. Roentgen radiation should be given over longer periods of time with better filtration, because the vascularity which it induces increases the oxygen potential in the tissues and hinders the growth of the anaerobic actinomycete.

As a case of cervicofacial actinomycosis may come under observation any time from three months to two years after the appearance of the initial lesion, all these factors should be taken into account before a decision is made in regard to the type of treatment to be given.

SUMMARY

1. Sixteen cases of cervicofacial actinomycosis are reported, 1 aerobic and 15 anaerobic in type.
2. Available evidence indicates that granule formation is an antibody-antigen reaction of the actinomycete to unfavorable environmental conditions in the host. Primary cutaneous actinomycosis can be caused by aerobic actinomycetes (nocardia), as is shown by cultural evidence from a case cited.
3. Roentgen therapy and oral administration of drugs to combat infection have proved adequate in uncomplicated cases of the anaerobic type of cervicofacial actinomycosis. If osteomyelitis of the mandible occurs orthopedic surgical intervention or even plastic surgery may be necessary.
4. We have found that the best treatment consists of filtered roentgen radiation applied locally, with sulfadiazine given by mouth. Penicillin has proved valuable in some cases, but it is more expensive than the sulfonamide drugs and must always be administered in large doses over long periods of time.

ABSTRACT OF DISCUSSION

DR. GEORGE M. LEWIS, New York: To have a series of 16 cases of actinomycosis is an unusual experience. Lamb and his associates have done well in this presentation to combine a review of the literature and also to report a careful study of their cases including laboratory confirmation. A clinical feature which should always be thought of as characteristic of actinomycosis is the development of sinuses, which in the absence of other known cause should always be suggestive. Without the development of the sinus tract, actinomycosis is not probable. I would also like to emphasize that a simple method for the laboratory diagnosis of this disease is also the best. A sample of pus is dropped on a clean glass slide and a cover slip applied. Staining is not required and if used is apt to produce distortion. If examined in transmitted light it may be possible to distinguish the colony. The difficulty of carrying out cultural studies precludes this method of study from universal use. This paper is particularly valuable because Dr. Lamb and his associates had the opportunity of evaluating various methods of treatment. From their conclusions we would gather the impression that they favor the retention of roentgen radiation combined with sulfadiazine therapy; in selected cases one may add penicillin therapy, although by no means relying on that alone.

DR. FRED D. WEIDMAN, Philadelphia: Dr. Lamb has described a new species of Nocardia in a case of primary actinomycosis. The item which has aroused the most interest has been the high percentage of cures; something quite different from what is customary. That makes one wonder. Was the fungus a pathogenic strain? For a long time it has been known that there are forms of actinomycetes saprophytic not only in the tonsils of hogs but also in those of man, even though it has been determined recently that *some of the latter were the* genuinely pathogenic Actinomyces bovis. A personal experience is in point. While I was experimenting with cutaneous torulosis in the monkey, I coughed a pellet of mucus from my bronchus. It recalled the mucinoid material which I had observed in monkeys' experimental lesions, and both under the microscope and in culture I demonstrated the fungus. An internist found no physical signs and advised me not to worry about it. He admitted that he did not know anything about mycology but stated on general principles that there was no reason why fungi should not occur in attenuated form, as is the case for bacteria. This happened about ten years ago. At the Philadelphia Zoological Gardens an abscess developed alongside the nose of a monkey, rather close to the eye. In the pus I found ray fungi with clubbing. It is difficult to treat these lower animals. I tried to work some iodine into the milk, but the monkey would have none of it. I injected iodine as best I could into the sinus. It was not very successful, but the monkey went on merrily to a cure. The position of the abscess was over the root of the incisor; such teeth have extremely long roots, and the apex corresponded to the position of the abscess. It was the old story of an apical abscess eroding through to the cheek. In my judgment, the attempts at treating the monkey were useless and the lesion regressed spontaneously. Perhaps here again the strain of Actinomyces was an attenuated or saprophytic one. I agree entirely as to the significance of the material which constitutes the clubs, namely that it is a reaction against an unfavorable environment. This material is elaborated jointly by the tissues and the fungous cell. There is a certain parallelism to Torula histolytica, with its mucinoid envelop. The latter will develop in a limited way, even in the absence of host tissue, on Sabouraud's medium; but if one increases the unfavorableness of the environment by growing it in the incubator, the envelop will develop much more promptly and massively. This proves that the material is in part at least, and in my opinion largely, a development on the part of the micro-organism.

---

[26] Thoma, K. H.: Oral Pathology, St. Louis, C. V. Mosby Company, 1941, pp. 849-851.

Dr. D. Truett Gandy, Houston, Texas: Actinomycosis has long been thought of as a Western disease associated with country life, but it has no geographic limitations and is as prevalent in urban as in rural populations. It is widely distributed in the United States. Although a rare disease, with the improved methods of diagnosis available today other mycoses are being transferred to the actinomycotic group. Cervicofacial infection in this disease is the common form, and the mandible is the common primary site. That trauma is a predisposing factor seems indisputable. Since the ray fungus is a normal inhabitant of many mouths, and trauma occurs in all mouths, obviously a third factor must be necessary for infection, namely, sensitization. Differential diagnosis must exclude all forms of infectious granuloma, inflammatory masses and tumors. The patient may complain early of facial pain, which has been mistaken for trigeminal neuralgia. Frequently a dentist is consulted for toothache. I know of more than 1 case in which teeth were pulled, and usually with benefit, since it helped to establish drainage. In the cervicofacial lesion, syphilis, tuberculosis and carcinoma must be excluded. Perhaps the most commonly made errors are diagnoses of tuberculosis, cancer and dental root abscess. One must not forget that actinomycosis and carcinoma have been reported in the same patient, just as syphilis and carcinoma may coexist, notably in the tongue. Because the clinical history and findings in most cases are not pathognomonic, one must depend almost entirely on laboratory studies for a final diagnosis. The finding of the ray fungus in pus from a sinus tract or abscess or its histologic demonstration from biopsy or autopsy material is, of course, conclusive. Lesions in the face and neck offer a much more favorable prognosis than actinomycosis elsewhere in the body, due to their accessibility and the greater likelihood of early recognition.

Dr. William J. Morginson, Salt Lake City: At Bushnell General Hospital 12 patients with actinomycosis were treated with penicillin. One patient was moribund when admitted to the hospital. Actinomyces was recovered from his sputum, from a subdiaphragmatic abscess and from a knee joint. After the administration of 8 million or more units of penicillin and prolonged hospitalization; he was returned to full duty. While treating these actinomycotic patients with penicillin, patients in a comparable series were treated with massive iodide therapy, 500 grains (32.4 Gm.) per day, roentgen therapy and thymol. All the patients in both series recovered, as judged by follow-ups of eight months to a year. It was concluded that penicillin is an effective agent against actinomycosis but not any more effective than older methods of treatment with iodides, roentgen therapy and thymol. However, in the case of the previously mentioned moribund patient penicillin was apparently lifesaving, as it is doubtful if other methods would have been effective.

Dr. C. Guy Lane, Boston: As Dr. Lamb has shown, there are comparatively few cases of actinomycosis in Massachusetts; but several years ago I had a case which brings out two points pertinent to this discussion. A man aged 50 had an extensive actinomycosis of the right side of the face and neck, and eventually of the left side, which had been present for several years before my associates and I saw him, although the diagnosis had not been made. Drs. Swartz and Rockwood concluded that it was due to A. bovis. He did not respond to either iodide or large doses of filtered radiation. He was under study for some time. Eventually his infection responded to combined doses of a sulfonamide compound, I believe it was sulfadiazine, and iodides. The lesions disappeared, and any discharge was persistently negative. As time went on, however, he had a good deal of contraction, probably from the disease and perhaps from the extensive radiation that he had, so that he was unable to open his mouth more than enough to insert a throat stick. He lost weight and strength and became very thin. No lesions were appearing and nothing was active by roentgen examination. Eventually the oral surgeon operated on him, cut some scar tissue and lengthened the muscles, so that he was able to eat satisfactorily and gain weight. The two points that I wish to emphasize in this case are, first, the fact that before the days of penicillin the infection responded to conjoint iodide and sulfadiazine therapy, and, second, the complication of persistent scar tissue which needed operative correction.

Dr. Stephen Rothman, Chicago: From Dr. Lamb's presentation I would draw the conclusion that an effective chemotherapy of this severe disease has not been found. In Hungary where the disease is rather common in the rural population I experienced several waves of initial enthusiasm about therapy with new methods, such as vaccines and injections of gold. Disappointment followed soon. Lately I went through a similar wave of enthusiasm with sulfonamide compounds. They obviously have an influence on secondary infection only. Roentgen rays are not fungicidal. They only reduce the amount of granulation tissue and thereby create less favorable conditions for the ray fungus.

Dr. John H. Lamb, Oklahoma City: Dr. Weidman suggests that our percentage of cures in this disease is much higher than that encountered in the East. The criterion for cure in actinomycosis appears to be early diagnosis and early treatment. It has been our good fortune that a great percentage of our cases were sent by two exodontists who made a diagnosis early and sent the patients to us for treatment before the infiltrations were widely spread. The cases which have not been cured have been ones of long duration, which were treated by various other methods before the patients were seen by us. In answer to Dr. Gandy's remarks, roentgen therapy must often be started before one has a microscopic confirmation of the diagnosis, which must be made clinically without delaying the start of treatment, since each day the disease becomes more difficult to cure. Many times we have not found the granules until the thirtieth day of treatment. Dr. Morginson suggests that penicillin is a good treatment for actinomycosis. This is true in a certain percentage of cases. When it does work the results are indeed dramatic, and I must stress that high dosage levels over prolonged periods are indicated.

Clinical Notes, Suggestions and New Instruments

MELIOIDOSIS

Report of First Case from the Western Hemisphere

FRANK McDOWELL, M.D.
and
PHILIP L. VARNEY, Ph.D.
St. Louis

Melioidosis is a specific infection caused by the glanders-like bacillus, Malleomyces pseudomallei. This organism usually produces an acute pulmonary and septicemic form of the disease, with multiple miliary abscesses in the viscera and with early death, but occasionally causes a chronic form, with multiple sinuses of the soft tissue, which is similar to glanders. About 300 cases have been reported, nearly all of them from the Far East. Krishnaswami[1] observed 200 cases in Rangoon and others have been reported from elsewhere in Burma, the Federated Malay States, Indo-China, Siam, Ceylon and the Dutch East Indies. Grant and Barwell[2] observed a chronic case in England in a British soldier who contracted it in the island of Penang. Mayer and Finlayson[1] reported a chronic case from South Africa in a soldier who contracted it in the island of Singapore. Cox and Arbogast[3] recorded an instance of the disease in an American soldier in Burma. Mirick and his associates[1] reported 2 cases in American military personnel in Guam. It is believed that our patient is the first one to be reported from the Western Hemisphere.

The disease was first discovered and the organism identified in Rangoon by Whitmore in 1912. In the Far East it is primarily a disease of rodents, but it is often impossible to demonstrate it in rats in the immediate area in which cases occur in human beings. The mode of transmission is unknown, though some believe it is probably by contamination of foods with the excreta of rats. Blanc and Baltazard[5] have demonstrated experimentally that the disease can be transmitted by the Aedes aegypti mosquito and the rat flea, Xenopsylla cheopsis. Human to human transmission has not been reported.

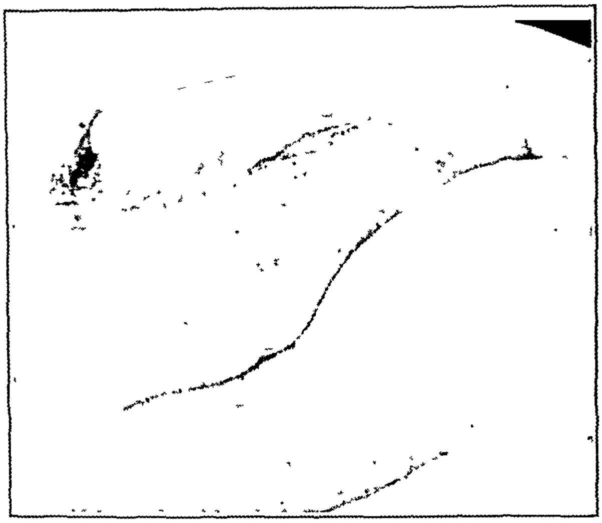
No cures have been reported, though some patients with the chronic form of the disease were greatly improved at the time when their cases were reported and may have since recovered. Penicillin has been used in large amounts in several cases, including ours, without effect. The organism is decidedly sensitive, at first, to sulfadiazine in vitro, but this drug did not help our patient. Grant and Barwell's patient seemed somewhat better when he was taking sulfadiazine, but the temperature went up again each time that administration of the drug was discontinued. At the suggestion of Dr. Jacques Bronfenbrenner and Dr. Barry Wood, streptomycin was tested both in vitro and clinically on our patient. In vitro, the organism, which was extremely sensitive to this drug at first, rapidly became quite resistant; clinically, the patient did not seem to benefit from streptomycin therapy.

The acute form of the disease is often not diagnosed until the postmortem examination. There seems to be nothing particularly characteristic about it, as the symptoms and signs which are usually noted are a sudden onset with high fever, prostration, signs of bronchopneumonia (sometimes hemoptysis), generalized aching pains, diarrhea, lymphadenopathy, collapse and death, which often occurs on the third to the seventh day of the disease.

Of the 8 chronic cases reported, all but 2 developed as a sequel after the patient had survived the acute form of the disease. These patients have chronic ulcers, with subcutaneous and deeper sinuses burrowing out from them and ending in tender, granulomatous nodules, which later break down into abscesses. It somewhat resembles glanders and generalized mycosis.

REPORT OF CASE

History.—W. M., a white man aged 31, entered Barnes Hospital on Oct. 6, 1945 with ulcers and sinuses of the right buttock and thigh of eight years' duration. His story began when he fell, injuring his coccygeal area. Three days later he had a tender, dark swelling in this area, which was incised by his local physician, who thought it was an infected pilonidal cyst. The lesion has not been healed since this time. After the incision he was in the hospital eleven days but was not extremely ill. Three days after he left the hospital he collapsed in the street, and for the next thirty-nine days, unconscious with a high fever, he was in his local hospital. After he regained consciousness, he remained in this hospital for three years and eight months, having seventy-eight drainage operations for abscesses about the right buttock and thigh from the iliac crest to the knee, posteriorly. Since he left there, he has been in a number of the leading clinics and hospitals of this country and has had almost every known form of therapy. He has had numerous courses of sulfathiazole, sulfapyridine and sulfadiazine, usually taking 5 to 6 Gm. a day, but has had to stop each time in three weeks or less because of cutaneous rashes, nausea and vomiting. He thought that the sulfonamide drugs had not helped him. A few months before entry at Barnes, he had undergone an operation in which "14 pounds of flesh and eight abscess sinuses" were removed, and this seemed to help him more than anything tried previously. Amputation had been considered, but the area of involvement seemed too widespread for even an interinnominate one.



Posterior view of right buttock and thigh with patient lying on his left side. Some of the numerous scars of old incisions and tunnels may be seen, showing that the area of involvement is much greater than the surface ulceration.

Much of his past life had been consumed by illnesses, including poliomyelitis with six corrective foot operations, spinal meningitis, typhoid, scarlet fever, diphtheria, whooping cough, measles, chickenpox, mumps, trachoma, a tonsillectomy and a mastoidectomy. He had worked as a machinist and had lived in Oklahoma, Missouri and Illinois, except for 1927 and 1928,

when he was employed in the Panama Canal Zone. Four years ago his weight was down to 119 pounds (54 Kg.), but he has since regained his average weight of 200 pounds (91 Kg.). He has had "bronchial asthma" for the last few years.

Physical Examination.—The patient was moderately obese, had a sallow complexion and was able to walk with some difficulty and considerable pain. There were several chronic, granulating ulcers on the right buttock and thigh, with some subcutaneous tunnels extending out from them. These tunnels ended in tender subcutaneous swellings. The granulations on the ulcers were coarse and gray, but opposite the mouths of the tunnels, where the secretions poured out onto the granulations, they appeared to have been coagulated by heat or caustic chemicals. In some places, where the secretions had apparently drained across the ulcer and onto the normal skin on the other side, this skin was etched as though by some corrosive. The inguinal lymph nodes on that side were swollen and tender but had not been incised. Motion in the hip and knee joints was not restricted, and roentgenograms appeared to reveal normal conditions. Cutaneous sensation was normal except immediately adjacent to active lesions or old scars.

There were a few wheezes and sibilant rales over the two upper lung fields. Roentgenograms of the chest showed only some increase in hilar markings and peribronchial thickening. The reflexes were physiologic, and the remainder of the examination was negative except for the poliomyelitis residual in one of the feet.

Laboratory Examinations.—Urinalysis was negative, and the nonprotein nitrogen of the blood was 17 mg. per hundred cubic centimeters The white blood cell count varied from 5,500 to 15,000 with a slight lymphocytosis in the differential. The red blood cell count was 4,600,000 and the hemoglobin was 13 Gm. on entry, but a moderate secondary anemia repeatedly developed in the patient, and he required transfusions of blood several times during his stay. The serum protein level was 6.4 Gm. per hundred cubic centimeters, and smears for malaria were negative. The mallein ophthalmic test was negative.

Course.—A prolonged attempt was made to get the granulating areas clean, fine and bright red by daily scrubbing with soap and water and pressure dressings with fine mesh gauze next to the wounds. They improved but did not assume a healthy appearance suitable for a skin graft. Local applications of the various dye antiseptics, parachlorophenol, tyrothricin, chlorazodin, zinc peroxide, hydrogen peroxide, sulfonamide drugs, Dakin's solution, isotonic solution of sodium chloride, iodoform, peruvian balsam, merthiolate ointment, xeroform ointment, scarlet red ointment and petrolatum were tried at various times in conjunction with the previously mentioned treatment. None seemed to benefit the patient much, though he seemed to do better on a combination of 10 per cent merbromin and 1 : 2,000 merthiolate ointment than on anything else. Several nodules were drained and tunnels laid open, and in November the thigh portion was covered with split grafts which took almost completely. Cultures had been taken from the tunnels and granulations on several occasions for routine laboratory examination. Various types of staphylococci, nonhemolytic streptococci, Proteus ammoniae and Bacillus pyocyaneus were reported. In January a new nodule was opened, and one of us (P. L. V.) isolated M. pseudomallei from the contents in large numbers.

After in vitro tests, the patient was given 16 million units of streptomycin intramuscularly (4 million for two days, 2 million for one day and 1 million for six days) without any demonstrable improvement. Prior to this he had received large amounts of penicillin without effect, and sulfadiazine therapy had been tried but discontinued because it caused nausea, vomiting and a cutaneous rash.

Subsequent to streptomycin therapy, the remaining nodules and sinuses were opened, and in February a widespread cautery excision of the buttock and upper thigh was performed, removing all the skin, the subcutaneous fat, most of the gluteus maximus and part of the hamstrings. The excision seemed to be well out into normal tissue, and afterwards the pain of the patient diminished and his temperature (which had remained constantly between 39 and 40 C., 102 and 104 F.) fell almost to normal. The granulations which developed seemed quite clean, and in April the area was covered with split-skin grafts. The grafts took every place except at the top of the wound. This remaining area was excised with the cautery in June and was grafted early in July. Most of the graft took, but the patient still had some small granulating areas when he was discharged July 21, 1946. At this time, he had not had any new sinuses or nodules for some months and was so much better generally that we could not persuade him to remain longer, though we did not feel that he was free of the disease.

Bacteriologic Studies.—The organism was recovered repeatedly from blood agar cultures of pus and tissue débris, but cultures of the patient's blood and sputum were negative. The organisms from both the smooth and rough colonies were poorly staining, bipolar, gram-negative and non-acid-fast, and under suitable conditions they exhibited rapid serpentine mobility. Those from rough colonies averaged 2 by 0.6 microns in size, while those from smooth colonies were usually longer and narrower, occasionally reaching a length of 5 to 6 microns. In stained preparations they exhibited decided parallelism and were usually arranged in an irregular network. The bacilli appeared encapsulated, especially in freshly isolated cultures or animal lesions, but no capsules were demonstrated by staining. The organisms resembled Malleomyces mallei, except that they were motile, while the colonies exactly resembled those of M. pseudomallei as described by Topley.

Growth was strictly aerobic, and the organisms grew rapidly and profusely on all commonly used mediums at 24 to 37 C., development being especially good on mediums with a tryptose base and better on blood agar than on plain agar. On blood agar, corrugated forms developed into smooth or only slightly roughened colonies, rarely larger in diameter than 3 to 4 mm., which were entire, hemispherical and mucoid. Colonies of the smooth form were entire, convex and mucoid and often grew to a diameter of 8 mm. The colonies were initially grayish white but changed to a deep brown. The colonies were surrounded by a narrow inner zone of complete hemolysis and a larger zone of diffuse hemolysis.

An extended examination of the organism was made to establish its identity, complete cultural and morphologic characteristics and behavior in animals, as well as the in vitro effect of various chemotherapeutic agents and antibiotics on it. These data will be published in detail in the bacteriologic literature.

COMMENT

It is interesting that Grant and Barwell's patient and Mayer and Finlayson's patient also had involvement of the right buttock and hip region, though in both there later developed osseous lesions. Our patient did not have any demonstrable lesion of the bone on several roentgenograms which were taken during the period of observation.

The occurrence of an isolated case of this disease in the interior of the United States is not easily explained. There is no history of any animal bites or unusual exposure to insects, and the patient has never known any one else who had a similar disease.

SUMMARY

The first case of melioidosis occurring in the Western Hemisphere is reported. It was the chronic form, consisting of ulcers and sinuses about the buttock and thigh, but may have been preceded by an acute pneumonic phase. General therapy with sulfonamide drugs, penicillin and streptomycin was ineffectual. Local treatment with a wide variety of agents was of little benefit. Widespread cautery excision, followed later by skin grafting, seemed to be the most helpful form of treatment.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

In the interest of better controls to insure potency, purity and uniformity of finished products that are accepted for inclusion in N. N. R., the Council is now requiring manufacturers to supply more specific information on the test procedures that are used to control the composition of submitted products. The following statement, adopted by the Council, outlines for manufacturers the points on which the Council will henceforth require additional specific information on articles submitted for inclusion in N. N. R. This statement is now printed with the "Official Rules" of the Council, a copy of which will be furnished on request.

AUSTIN SMITH, M.D., *Secretary.*

CONTROL PROCEDURES FOR ARTICLES INCLUDED IN NEW AND NONOFFICIAL REMEDIES

Manufacturers must submit a statement of the control processes used for each product submitted to the Council. Unnecessary duplication may be avoided with subsequently submitted articles of one type by reference to the first general statement made concerning control methods employed for an article of that same class.

The description of control procedures should include information on each of the following points (where applicable):

(*a*) Precautions to insure proper identity, strength and purity of the raw materials.

(*b*) Precautions to preserve sanitary conditions in space allotted to storage of raw materials.

(*c*) Whether or not each lot of raw materials is given a serial number to identify it and the use made of such numbers in subsequent plant operations.

(*d*) Method of preparation of formula card and manner in which it is used.

(*e*) Manner in which weights and measures of each individual ingredient are checked when preparing formula.

(*f*) Whether or not the total weight or volume of each batch is determined at any stage of the manufacturing process subsequent to making up a batch according to the formula card and at what stage and by whom this is done.

(*g*) Methods of maintaining sanitary conditions within the manufacturing plant and avoiding contamination of the drug with filth, dust and extraneous material.

(*h*) Precautions to check the total number of finished packages produced from a batch of the drug with the theoretical yield.

(*i*) Precautions to insure that the proper labels are placed on the drug for a particular lot.

(*j*) The analytical controls used during the various stages of the manufacturing, processing and packing of the drug, including a detailed description of the collection of samples and the analytical procedures to which they are submitted. If the article is one which is represented as sterile, the same information should be given for sterility controls.

(*k*) An explanation of the exact significance of any control numbers used in the manufacturing, processing and packing of the drug, including any code numbers which may appear on the label of the finished article.

(*l*) Additional procedures employed which are designed to prevent contamination and otherwise insure proper control of the product.

(*m*) Are representative samples of each lot of the drug examined by any other laboratory (government or private) prior to distribution? If so, by whom?

PRESENTATION OF ARTICLES FOR N. N. R.

To facilitate the proper presentation of articles that are submitted for inclusion in New and Nonofficial Remedies, the Council has adopted the following statement as a supplementary guide to manufacturers to assist them in compliance with the Official Rules. Delay in obtaining prompt action on articles submitted for N. N. R. is frequently traceable to lack of required data and failure to comply with the rules. This statement is therefore provided to insure uniformity of understanding concerning the procedure to be followed and the type of information that is required for the presentation of articles that are eligible for inclusion in N. N. R. A reprint of this statement and copy of the Official Rules of the Council will be furnished to manufacturers on request.

AUSTIN SMITH, M.D., *Secretary.*

ELIGIBILITY FOR N. N. R.

Before submitting any article for inclusion in N. N. R., a careful study of the Official Rules and of N. N. R. should be made to determine its eligibility for acceptance by the Council. Articles of questionable eligibility may have their status determined prior to formal presentation on request of the manufacturer. Such preliminary requests directed to the Council office may avoid waste of time for all concerned.

New drugs, not yet released for commercial distribution by the Food & Drug Administration, will not be accepted until passed by that agency unless it seems evident that the product will be placed in interstate commerce. The Council restricts acceptance to articles that are available on the market or soon to be placed thereon and to articles that are marketed in the United States.

1. Articles belonging to a class of preparations already rejected by the Council and for which new evidence is lacking to overcome previous objections are obviously ineligible for inclusion in N. N. R. A cumulative list of references to reports of the Council on articles previously rejected or on which unfavorable action has been taken will be found in the Bibliographic Index of N. N. R.

2. Articles that have had official (U. S. P. or N. F.) status for more than twenty years (except products licensable under the Serums, Virus and Vaccine Act, including arsenicals for syphilis, which are admissible) or have been specifically exempted from consideration by previous action of the Council, are likewise in general ineligible for N. N. R. (Report of the Council: Preparations Exempt from Council Consideration, J. A. M. A. **129**:1017 [Dec. 8] 1945).

3. Articles advertised to the public without adequate directions for use or against abuse or that are not considered safe for use by the general population without medical supervision are ineligible for inclusion in N. N. R. Thus far the Council has classified as safe for public use (*a*) antiseptics for prophylactic application to minor injuries of the skin, (*b*) laxatives not prone to abuse, (*c*) antacids and analgesics that can be safely used for the temporary relief of symptoms.

4. Articles of nonmedical significance or that are not intended for the diagnosis, prevention or treatment of disease are not eligible for N. N. R. Thus, articles not used in or on the human body, or used outside the body for purposes that are not directly or indirectly of medical significance, would not come within the purview of the Council.

5. Instruments or devices per se that do not directly involve consideration of some medicinal or pharmaceutic substance are also outside the purview of the Council.

METHOD OF PRESENTATION

The procedure in submitting an article to the Council consists in forwarding to the Secretary: A complete description of the product (dated and signed) *in duplicate*, in accordance with the form outlined in subsequent paragraphs; three trade packages of each dosage form of the product to be considered (not to include more than one quantity package of identical lots of the same item); one sample of *each active ingredient* contained in the product; twenty-two copies each of all labels (container, package, carton), package enclosures (leaflet or circular) for each submitted dosage form and of *each piece of advertising* for the product that is distributed or intended for distribution. (Advertising for submitted articles that mentions other products not submitted or already accepted by the Council for inclusion in N. N. R. cannot be approved for distribution unless the advertising is revised to eliminate the unaccepted items.) Consideration is expedited if the labels are mounted on normal size letter paper so that twenty-two separate sets of labels will be available for examination. In the case of new drugs or of well known articles, for which new therapeutic claims are advanced, the outlined description should be supplemented by twenty-two copies of reprints (or suitable abstracts) of all available experimental and clinical evidence including references to the published scientific literature or other sources from which it is derived. The Council considers it the responsibility of the manufacturer to furnish evidence to support all claims made for products that it markets. When the article submitted represents only a new brand of a preparation already described in N. N. R., such evidence is not required so long as the claims do not go beyond the statements made in that publication. When the article is simply a dosage form of a brand of the product already accepted, only that information essential to supplement the original presentation of the article to afford a clear description of the composition and purpose of the new dosage form is required, in addition to the necessary specimens and copies of the labeling and any new advertising. When two or more dosage forms of the same product are submitted together, the information may frequently be combined in the same outline when that is feasible. The inclusion of unacceptable dosage forms (or mention of them in the advertising) in a presentation submitted for otherwise acceptable items of the same product frequently causes delay in acceptance of the recognized dosage forms. Separate outlines for dosage forms involving special vehicles or bases may avoid the confusion that sometimes arises in this connection. The Council has restricted acceptance of certain products to dosage forms of specific size or concentration that is indicated either in the Official Rules or in N. N. R. under the general statements for the class of articles affected.

OUTLINE OF DESCRIPTION

1. *Name of Product.*—The protected (trademark) or coined name, if any, should be supplied; otherwise the common name used to designate the product may be given. The common name should, when applicable, conform to the official (U. S. P. or N. F.) designation or the nonproprietary (generic) name adopted by the Council. Protected names should comply with all stipulations of rule 5 concerning acceptable nomenclature and should be followed at this point of the outline with a brief explanatory statement of the significance and reason for choice, together with the date the name was first used publicly to designate the product. (The Council does not recognize protected names that were not in public use prior to admission of the article to official status in the U. S. P. or N. F.) The name (protected or otherwise) should be reasonably descriptive if possible of the principal active ingredient, should include the designation of the salt when it is present in such form, and, when applied to specific dosage forms, should include an appropriate designation of the nature of the product and the quantity or concentration of the active ingredient, e. g. Tablets Phenobarbital, 0.1 Gm., Solution Phenobarbital Sodium 10 per cent. Likewise, certain ingredients that may be present in sufficient amounts or concentration to produce a prominent, though secondary, therapeutic effect (intended or otherwise) are required to be declared as part of the name for the product, e. g. Solution Sodium Morrhuate 5 per cent with Benzyl Alcohol 1 per cent. Care should be taken that the name given and its word order corresponds to that shown on the submitted labeling and advertising.

2. *Synonyms.*—The official or N. N. R. name that may be used for prescribing when a protected or coined name is used to designate the product should be submitted; if marketed only under an official, Council-adopted or common or generic name, any other appropriate synonym that may be applicable is satisfactory. When a protected name is used, and an official or Council-adopted nonproprietary name does not exist, one or more suggested nonprotected names suitable as a generic designation should be submitted for consideration by the Council's Committee on Nomenclature. In all cases when a protected name is used, the official or N. N. R. name is required to be displayed on the labeling and advertising, with sufficient prominence to permit ready identification of the product, e. g. Tablets Luminal (Brand of Phenobarbital), 0.1 Gm.; Solution Luminal Sodium (Brand of Phenobarbital Sodium), 10 per cent.

3. *Definition.*—If the article represents a definite substance, its scientific name and its structural chemical formula so far as this can be ascertained must be submitted. If the article is a mixture, or is submitted in the form of tablets, solution, ointment or the like, a quantitative statement of composition of all active medicinal ingredients, including preservatives, vehicle, base or excipient, preferably in percentage form (when applicable) and in the metric system should also be offered. Unless otherwise indicated, per cent figures will be understood to follow the meaning of percentage as defined for the U. S. P. Labeling should carry a quantitative declaration of all active ingredients unless this is clear from the name used to designate the product and, in the case of injectable preparations, must include a declaration of the presence of any preservatives that are added. The identity of the vehicle or base in the case of solutions, suspensions or ointments not self evident from the name should be specifically stated on the label. In the case of biologic products for injection or topical application to denuded surfaces, the Council encourages the declaration of the animal source of the material because they are capable of precipitating allergic reactions in sensitive persons.

4. *Preparation.*—The description should contain a general statement of the process of manufacture. Details of the process may be omitted, but sufficient description is to be included to enable the Council to assure itself that the process will result in a product of the claimed identity, strength, quality and purity. Particular attention should be paid at this point to indicate all control procedures used to detect errors in manufacture and to insure the satisfactory character of the finished product. The Council requires detailed information concerning the methods used to control the potency and composition of each dosage form that is submitted. Information required on control procedures is outlined under this heading with the Official Rules of the Council.

5. *Properties.*—Appearance, odor, taste and any characteristic physical-chemical properties such as melting point, boiling point, solubility and any important incompatibilities must be stated.

6. *Tests.*—If the article is a chemical substance, there must be submitted adequate tests of identity, strength, quality and purity, including methods of assay. Upper and lower limits of acceptability for ingredients assayed are to be indicated. If the product is a mixture, methods for identification and assay of principal active ingredients are necessary. For vitamin preparations or other substances which must be biologically assayed, protocols of several typical assays, signed by a reputable biological chemist or other qualified assayist, should be presented. If the article is one which is represented to be sterile or because of its manner of use should be sterile, the methods used to determine its sterility, including method of sampling, bacteriologic method, frequency of examination and other pertinent information should be given. All methods should be described in accordance with the style of N. N. R. or of the U. S. P.

7. *Pharmacologic Action.*—General information is necessary concerning the absorption, actions, toxicity and fate or excretion of the preparation, particularly as applied to the manner in which it is intended to be used, i. e. by injection, oral administration or topical application. In the case of disinfectants, antifungal agents or spermicides the appropriate experimental tests made to demonstrate the efficiency of the product should

be outlined. Details of certain pharmacologic, bacteriologic or biologic tests that are required by the Council are described with the Official Rules. When such data are required for specified classes of articles or when the product is a new drug, these detailed reports should be separately compiled (in abstract form if extensive) and twenty-two copies supplied as a supplement to the information given under this heading.

8. *Therapeutic Indications.*—A brief statement of the conditions and/or diseases in which the article is claimed to be indicated is necessary. This should include any diagnostic and prophylactic as well as therapeutic uses. These should correspond to the actions and uses given in N. N. R. when applicable. If additional claims are advanced or if the article is a new drug, all claims must be supported by the pharmacologic or bacteriologic evidence given in the preceding section and by clinical studies to be outlined under this heading. The type of clinical evidence required is set forth with the Official Rules. In general, this should include a summary of the various conditions treated, the number and type of cases treated, the dosage, frequency and duration of the administration of the drug, the therapeutic effects and any untoward reactions observed. The actual clinical data, including a bibliography, should be furnished as a separate supplement to this part of the presentation, accompanied with twenty-two copies of each protocol, reprint or other suitable reproduction of the evidence. When extensive, the detailed reports may be submitted in duplicate and twenty-two copies of a suitable comprehensive and unbiased summary or abstract furnished for the Council. Care should be taken to see that the therapeutic claims that appear in the advertising for the product correspond to the indications and evidence given in this presentation.

9. *Dosage.*—When applicable, the dosage and method of administration recommended should correspond to the one specified in N. N. R. When the product is a new dosage form of an article otherwise described in N. N. R., the details of dosage and administration for the proposed product should be given, together with any necessary precautions peculiar to its mode of application. Similar care should be taken to supply all essential dosage information for a new drug.

10. *How Supplied.*—A list should be given of all dosage forms, sizes and package forms of the article that are intended for consideration by the Council and that are described in the foregoing outline. A statement should also be included to indicate whether or not the active ingredient is marketed in bulk.

11. *Manufacturer.*—The name of the firm that is responsible for the finished article as labeled and the names of the manufacturers of all ingredients contained in the article must be stated.

12. *Patents and Trademarks.*—When pertinent, the number of the U. S. patent and number of the patent in the country of origin is necessary. If the article bears a registered trademark, its number and, if registered in foreign countries, the name or names under which it is so registered is also required.

Firms submitting for the first time an article eligible for inclusion in N. N. R. are required to supply the following additional information (*in duplicate*) at the time the first such presentation is made to the Council:

(*a*) Price list or other suitable tabulation of all products sold by the firm for human medicinal use.

(*b*) A statement of the laboratory and control personnel of the firm and their qualifications.

(*c*) A general statement of the firm's policies with respect to its scientific aims and methods of marketing drugs either for the public or for the profession. This should include present practices as well as any future plans.

(*d*) A statement, signed by a responsible officer of the firm, that it agrees to notify the Council promptly on the discovery that an error has been found in the compounding of any of its Council-accepted preparations, either by the firm itself or by a government or other outside agency, that causes the article to differ from its standard of identity, strength, quality or purity.

(*e*) A statement, also properly authorized, that the firm agrees to abide by the rules of the Council as applied to brands of its articles that may be accepted for inclusion in N. N. R. and to submit to the Council before implemented all future proposals for changes in the composition, labeling, advertising or market status of such products.

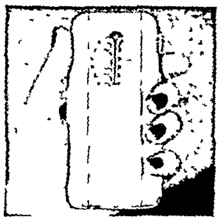
Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

PARAVOX HEARING AID MODEL XT ACCEPTABLE

Manufacturer: Paraphone Hearing Aid Company, 2056 East Fourth Street, Cleveland 15.

This instrument is self contained, batteries being inserted in the back of the case. The case is of pressed metal in three parts —one front and two back pieces. One of the back pieces slides off for battery replacement, the other for chassis change. The wearing clip is centered in the slotted grill over the microphone. The volume control and "on-off-tone" switches are placed at the upper corners of the instrument. One receiver, a crystal type, was supplied. Three "tone" selections are readily available.



Paravox Hearing Aid, Model XT.

Dimensions and Weight

Single unit with batteries: 5⅛ by 2⁷⁄₁₆ by ¾ inch (13.0 by 6.2 by 1.9 cm.), weight 6.2 ounces (175 Gm.).

Battery Data		Measured Voltage	Measured Current
A	1½ volts	1.3 volts	60 milliamperes
B	30 volts	28 volts	0.8 milliampere

Acoustical Gain

Measurements of the gain in decibels in the sound pressure level referred to 0.0002 dyne/sq. cm. attached to a 2 cc. coupler over the pressure levels at the microphone were made at nineteen frequencies between 200 and 4,096 cycles per second with the input level set at 0.02 dyne/sq. cm. The following figures are typical of the gains in decibels when the volume control was set full on:

Frequency.......	256	512	1,024	1,200	2,250	3,100	4,096 cycles
Tone controls							
"1 dot"........	35	47	52	57	42	43	48 db.
"3 dots".......	21	33	38	42	24	24	27 db.

Approximate values of maximum pressure levels at four frequencies observed on a 2 cubic centimeter coupler, with volume control set for full gain and the "two dot" tone setting:

Frequency	Input Level	Maximum Output Level
600 cycles	65 decibels	103 decibels
1,024 cycles	81 decibels	107 decibels
1,400 cycles	80 decibels	113 decibels
2,048 cycles	70 decibels	99.5 decibels

The usual articulation and intelligibility tests were made with a hard-of-hearing subject and showed a syllable articulation of 94 per cent and sentence intelligibility of 100 per cent. The whispered voice was understood at a distance of 5 feet.

The Council on Physical Medicine voted to include the Paravox Hearing Aid, Model XT, in its list of accepted devices.

SATURDAY, MAY 24, 1947

WORK OF CIVILIAN PHYSICIANS DURING WORLD WAR II

Elsewhere in this issue (p. 369) appears a final report on the replies to the questionnaire developed by the Committee on National Emergency Medical Service on Medical Care of Civilians During World War II. The facsimiles of the questionnaire show the composite replies to each question in percentages of 2,322, the number of returned questionnaires used in the analysis. All statistical tests indicate that the 2,322 replies constitute an extremely good cross section of the physicians who remained in civilian practice during the war period.

The most depleted specialties during the war were internal medicine, surgery, pediatrics and orthopedic surgery. The patient load in 1944 was about three fourths greater than in 1941. This increase strongly suggests that the medical profession was probably more overworked than any other group of civilians. The sharp rise in the average income of physicians during the war period is explained by this increase in patient load. About 4 per cent of the civilian physician's time was devoted to Selective Service board examinations. Of the replying physicians 68 per cent approved a proposal that all qualified physicians in the community be required to serve on Selective Service boards in the event of another national emergency; 20 per cent said No and 12 per cent passed up the question. The Committee asked *the civilian practitioner, the only competent judge*, whether more physicians could have been spared for military service from his community. The response was 66 per cent No, 25 per cent Yes and 10 per cent No Answer. The footnote on question 42 indicates that a disproportionate number of No's came from physicians in towns under 2,500 and a disproportionate number of Yes's from physicians in individual practice in cities of over 1,000,000. Although 46 per cent reported that hospital facilities were unnecessarily depleted, 51 per cent did not attribute the shortage to military hospital construction. Seventy-four per cent hoped that in the event of another war military hospitals with idle staffs and beds in hard pressed civilian areas would be opened to civilian patients.

The replying physicians were favorably impressed by the method of deferment of medical and premedical students, as 70.3 per cent rated it Good or Fair. Also they thought well of the Procurement and Assignment Service, as 77 per cent rated it Good or Fair as it affected their communities. Only 53 per cent thought civilian nursing and technical personnel was unduly and dangerously reduced by induction into the armed forces.

In the event of another national emergency (1) 77 per cent favor the creation of a board representing the medical profession empowered to set the policy for the utilization of all physicians, (2) 50 per cent favor rotation between the armed services and civilian practice of all able bodied physicians below a reasonable maximum age despite the obvious administrative difficulties, (3) 60 per cent favor a national service bill that would require all physicians at reasonable ages to serve the government in some capacity in the armed forces or in civilian communities and (4) 81 per cent favor the formation of mobile civilian medical teams to supply areas stricken by epidemics and atomic or bacteriologic warfare. The No votes were 8, 38, 28 and 5 per cent respectively, the remainder of 100 per cent being No Answer.

The report to the Committee by the Bureau of Medical Economic Research on the replies to the first questionnaire from 26,000 discharged medical officers will be available on June 9 in Atlantic City. Obviously two questionnaires could not possibly cover all features of wartime medicine. Although some will doubtless question the competence of one or a few physicians to judge these questions of wartime medical supply and demand, both military and civilian, the recorded opinions of these many thousands of representative physicians about their military or civilian practices must command the attention of all people deeply involved in the unwanted task of preparing for another national emergency. A reasonable division of the scarce supply of medical services between military personnel and civilians must prevail.

Dickinson points out that civilian health during World War II was *extremely good even though* the 91 per cent of the population which remained civilian was served by less than 60 per cent of the medical practitioners; he lists some of the factors which explain the "riddle of supply." As an economist he calls this to the attention of those who are making extreme claims that a severe nationwide shortage of practitioners will exist after medical demobilization is substantially complete and even when the 10,000 to 15,000 discharged medical officers now in graduate training enter private practice.

ENDOMETRIAL TOXIN

In 1919 Obata[1] of the University of Tokyo showed that salt solution extracts of the human placenta are highly toxic for rabbits and mice. Within the limits of the experimental error extracts from the normal human placenta and from the placentas of eclamptic patients were identical in toxicity. He found that normal human serum can neutralize the placental toxin but that the antitoxic titer is low in eclamptic women. He concluded that eclampsia is an intoxication by the placental toxin made possible by a weakened antitoxic capacity of the maternal blood. The cause of this reduction of maternal antitoxin was not determined. His associates[2] found that a similar toxic product was produced by autolysis of the uterus.

Interest in Obata's toxic theory has been revived by Krichesky,[3] who recently discovered that saline extracts of pregnant and pseudopregnant rabbit uteri are highly toxic when injected intravenously into rabbits. Similar extracts of rabbit muscle, liver and nonpregnant uterus were nontoxic.

Following this renewed interest, Schneider[4] of the department of pathology of Stanford University undertook a quantitative study of the toxic effects of extracts from different portions of the uterus in different functional states from several animal species, with control tests of the toxicity of extracts of liver, intestine and skeletal muscle.

In mice, rats, rabbits and dogs an increase in tolerance could be built up by repeated injections of toxic extracts. After such preparation the animals survived the injection of as much as four times the normal minimum lethal dose of the extract. Within two days the acquired tolerance was completely lost in mice. Intramuscular, intraperitoneal and subcutaneous injection of multiple lethal doses were relatively nontoxic, though an occasional mouse developed convulsions and died after intramuscular injection.

Applying his routine mouse test, Schneider found that control extracts from the liver, small intestine and skeletal muscles of most animals thus far tested are nontoxic. Nontoxic extracts also were obtained from both pregnant and nonpregnant human myometrium and from the virgin uteri of the cow, sheep and rabbit. In contrast highly toxic extracts were obtained from human, cow and sheep placentas, and from the endometriums of man and all pregnant animals thus far tested. These placentas or endometriums often had a titer as high as 200 lethal mouse units per gram of tissue.

A number of the properties of the endometrial-placental toxin have been determined. Among the most important is its neutralization by normal blood or serum. A serum concentration of as little as 5 per cent causes a 50 per cent decrease in toxicity within an hour. Higher blood or serum concentrations completely neutralize the toxin. The toxic substance is not extractable in ether, acetone or alcohol. The extract is completely inactivated by heating to 75 C. for ten minutes. The product is nondialyzable through a cellophane membrane. The toxin is therefore presumably a protein and not the simple histamine-like substance described by previous investigators.[3]

During the course of this study 500 mice were injected with sublethal doses of the toxic extract from endometriums or placentas. Of these 175, or approximately 35 per cent, developed focal necroses of the liver.[4] The exact relationship between this toxin and the hepatic lesions has not yet been determined, since "spontaneous focal liver necrosis" in mice has been recently reported by other investigators.[5]

FAT METABOLISM

Until recently comparatively little has been known about the part fats play in general metabolism. In spite of numerous carefully designed experiments, the question as to whether fat, once formed in the body, is available for carbohydrate or protein synthesis could not be settled until isotopes had become available as tracers for metabolic work. Weinhouse, Medes and Floyd,[1] working at the Lankenau Hospital Research Institute, Philadelphia, attempted to find whether there is a short chained unit of fat metabolism around which anabolic and catabolic processes center. They reasoned that such a unit might correspond in fatty acid metabolism to pyruvic acid in carbohydrate metabolism; it might constitute the fragment from which synthetic reactions originate and to which degradation reactions proceed and might also be the unit through which interconversions between fats and other classes of foodstuffs take place. By substitution of this unit for the unwieldy fatty acids and of pyruvic acid for glucose, in vitro experiments in this field could be enormously facilitated. These workers were able to verify the suggestion existing for some time in the literature that a 2-carbon fragment plays some part in fat metabolism. This was established by studying ketone body formation from octanoic acid which had C^{13} synthesized into its carboxyl carbon. The ketone bodies, acetoacetic acid and beta-hydroxybutyric acid were isolated after the isotopic octanoic acid had been incubated for five hours in the presence of liver slices. An exhaustive analysis of these bodies revealed that C^{13} was present in approximately equal amounts in carbon atoms 1 and 3. These results could have been obtained only if octanoic acid broke down completely into 2-carbon fragments and the latter were resynthesized to the final 4-carbon form through random redistribution of these fragments.

F., and Weinhouse, Sidney: Fatty Acid Metabolism: IV Ketone Bodies as Intermediates of Acetate Oxidation in Animal Tissues, ibid. **162:** 1 (Jan.) 1946.

The role of this 2-carbon unit in fat metabolism and its transference from fat to carbohydrate and to certain amino acids has been established through the work of many investigators in many laboratories. As a result of these investigations it appears that fat formation is not an irreversible process. Fat is no longer regarded as a final storage form of excess food which can only be burned and converted to carbon dioxide and water, but it is now known to be a part of the great metabolic pool of the body to which these active fragments are continually being added and from which they are continuously being withdrawn for a great variety of other uses.

The role of the vitamins in the structure of coenzymes essential to some of these reactions is also being investigated. It was shown, for example, that insulin operates at one such step in carbohydrate utilization. A high degree of precision is obtainable in these experiments through the use of isotopes, by which individual molecules can be labeled and traced. Great strides will probably be made in the next few years in the understanding of normal processes concerned in these fundamental reactions as well as in the pathologic conditions that arise when individual components of the system are missing.

Current Comment

THE ANTIVIVISECTIONISTS CELEBRATE A PYRRHIC VICTORY

The antivivisectionists are indulging themselves with hysterical manifestations of happiness over a bill recently passed by the New York legislature and signed by Governor Dewey. The new legislation makes it illegal to steal a licensed dog and offer the animal for sale. The passage of this bill has been hailed all over the country as an antivivisectionist victory. Actually no reasonable person objected to the bill and it was wholly unnecessary anyway. The bill really duplicated existing legislation. Under the general laws of New York State protecting property rights the stealing of dogs was already a crime. There may be occasional criminals that steal people's pets; what they could get out of it by selling such animals to laboratories would hardly pay for the trouble. Any reputable research institution does its utmost to avoid receiving such animals. Perhaps some of the members of antivivisectionist groups are beginning to wonder what is being done with the funds that the executive secretaries continuously solicit. Those interested in protecting research cannot relax their vigilance. The fanatics will try to put over restrictive legislation of real significance on unsuspecting legislators just as soon as they see an opportunity.

REGISTRATION UNDER THE HARRISON NARCOTIC ACT

Physicians who are registered under the Harrison Narcotic Act or under the Marihuana Tax Act must effect registration on or before July 1 to avoid a penalty. Each year, despite the annual warnings in THE JOURNAL, this requirement is overlooked by some physicians and unpleasant consequences follow. Failure to register adds a penalty of 25 per cent to the tax payable and in addition subjects the physician to the possibility of a fine not exceeding $2,000 or to imprisonment for not exceeding five years, or to both. As an act of grace the Commissioner of Internal Revenue has in past years given some tardy registrants the choice between paying sums by way of compromise, a procedure authorized by law, or of accepting criminal prosecution. If this procedure does not produce the required promptness in reregistration, the commissioner will have no other alternative than to institute criminal prosecution.

VETERANS' MEDICAL CARE THREATENED BY REDUCED BUDGET

The tremendous advances made in the quality of medical services of the Veterans Administration in the past two years reflect the devotion of the new leaders to their ideals and the cooperation of the medical profession. When the war ended many physicians who could have returned to lucrative practice with full satisfaction for a duty well done elected to continue beyond the ordinary call of duty through service in the Veterans Administration. The enlistment of medical leaders meant more than appears on the surface, for it aided in causing many younger physicians to join the staff of the Veterans Administration. Thus the veteran himself benefited by the improved quality of medical personnel; less than 6,000 hospital beds have been closed for lack of staff. Even the closing of these beds was serious, but not nearly as serious as would have been the case had this program not advanced so well. Though the program was expanding in quality as well as in the number of patients to be served, the pace was maintained. An extensive outpatient program and a series of clinics were added, 25 per cent of whose patients would have otherwise had to seek hospitalization, even though outpatient treatment was more appropriate. The recent reduction by the Bureau of the Budget of the amount requested by the Veterans Administration to meet its needs seems to threaten alarmingly this whole achievement. Already the morale of staff is disturbed. The quality of service rendered by the Veterans Administration is today a leaven for the whole country. The budgetary needs to maintain that quality should be met to the full if far reaching disastrous effects are to be avoided.

ANALYSIS OF QUESTIONNAIRE ON MEDICAL CARE OF CIVILIANS DURING WORLD WAR II

FRANK G. DICKINSON, Ph D
Director of Bureau of Medical Economic Research
Chicago

FOREWORD

The Committee on National Emergency Medical Service requested Frank G. Dickinson, Ph.D., Director of the Bureau of Medical Economic Research, to prepare a summary of the results of our Questionnaire on Medical Care of Civilians During World War II. The interpretations are those of Dr. Dickinson. The results of the questionnaire sent to 50,000 discharged medical officers will be presented at Atlantic City.

EDWARD L BORTZ, *Chairman.*

The statistics contained herein are a final report on the questionnaires sent to 5,000 doctors selected at random who did not enter the armed services during World War II and who graduated from medical college in 1939 or earlier.

This second questionnaire is reproduced herewith An IBM punch card was prepared for each returned questionnaire and our analysis was made through the use of these punch cards. The questionnaires were mailed late in January and early in February 1947 to approximately 5,000 physicians selected at random from our punch card files. It may be assumed that at least one fourth of them were not members of the American Medical Association. The method of making the random selection was:

1. From the entire file of cards those with a serial number ending in 5 were selected. This group totaled approximately 18,000.
2. The cards of men who had been discharged from military service were eliminated from this group of 18,000 cards At this stage an unsuccessful attempt was made to eliminate the cards of doctors who were not in active practice It failed because our records were not abreast of wartime changes.
3. The cards of all men who graduated from medical college in 1940 or later were removed from this group of cards Approximately 11,000 cards remained in our sample.
4. The cards with even serial numbers in the tens position were selected. This reduced our random sample to 5,600 cards

Because of changes of addresses not having been made in our punch card file, 550 addresses could not be quickly found in the Directory Department The final list, then, was 5,050, resulting from this process of selection, which was essentially random

Approximately one half of the questionnaires were returned Since 150 of the 5,050 were returned for incorrect address, we assumed that 4,900 doctors were reached The first mailing of the questionnaire brought approximately 1,900 returns; a follow-up was sent to approximately 2,900, some of whom had doubtless received and returned their questionnaire from the first mailing; a check could not be made because not all replies recorded the doctor's name and address Approximately 400 additional replies came in after the follow-up letters were sent; 228 returned questionnaires were not usable; most were from doctors who had retired from active practice who stated that they did not think they should answer the questionnaire (The random selection presumably obtained a cross section of retired doctors as well as those in active practice) We were able to use 2,322 of the returned questionnaires in this analysis

The number of usable replies was 47 per cent of the 4,900 doctors contacted. The usable plus the nonusable returned questionnaires was 52 per cent of the doctors contacted The number of usable replies was 50 per cent of the number of doctors contacted less the number of doctors who sent unusable replies. Approximately one half of the doctors reached did reply.

COMPOSITE REPLIES TO EACH QUESTION

In this analysis I shall use the question numbers as they appeared on the questionnaire. These numbers also refer to punch card columns. The first question, 5-8, asked for the name of the medical school from which the doctor graduated. More replying doctors gave Rush Medical College of Chicago than any other medical college. The first ten leading colleges are shown in table 1.

No future reference will be made in this report to the distribution of the colleges represented.[1]

On questions 9-10 and 11-12 the average (mean) year of graduation was 1918 and the average (mean) year of birth was 1892.

Starting with question 13 and continuing throughout the remainder of the questionnaire, I shall summarize the replies in terms of percentages of 2,322, the number of usable replies. Not all persons who answer any questionnaire will answer every question; this one was no exception to this rule. Hence I will show the percentage of No Answers. It will be necessary for the reader to compare each percentage against another percentage and not against 100 per cent if there was a percentage of No Answers to the particular question involved.

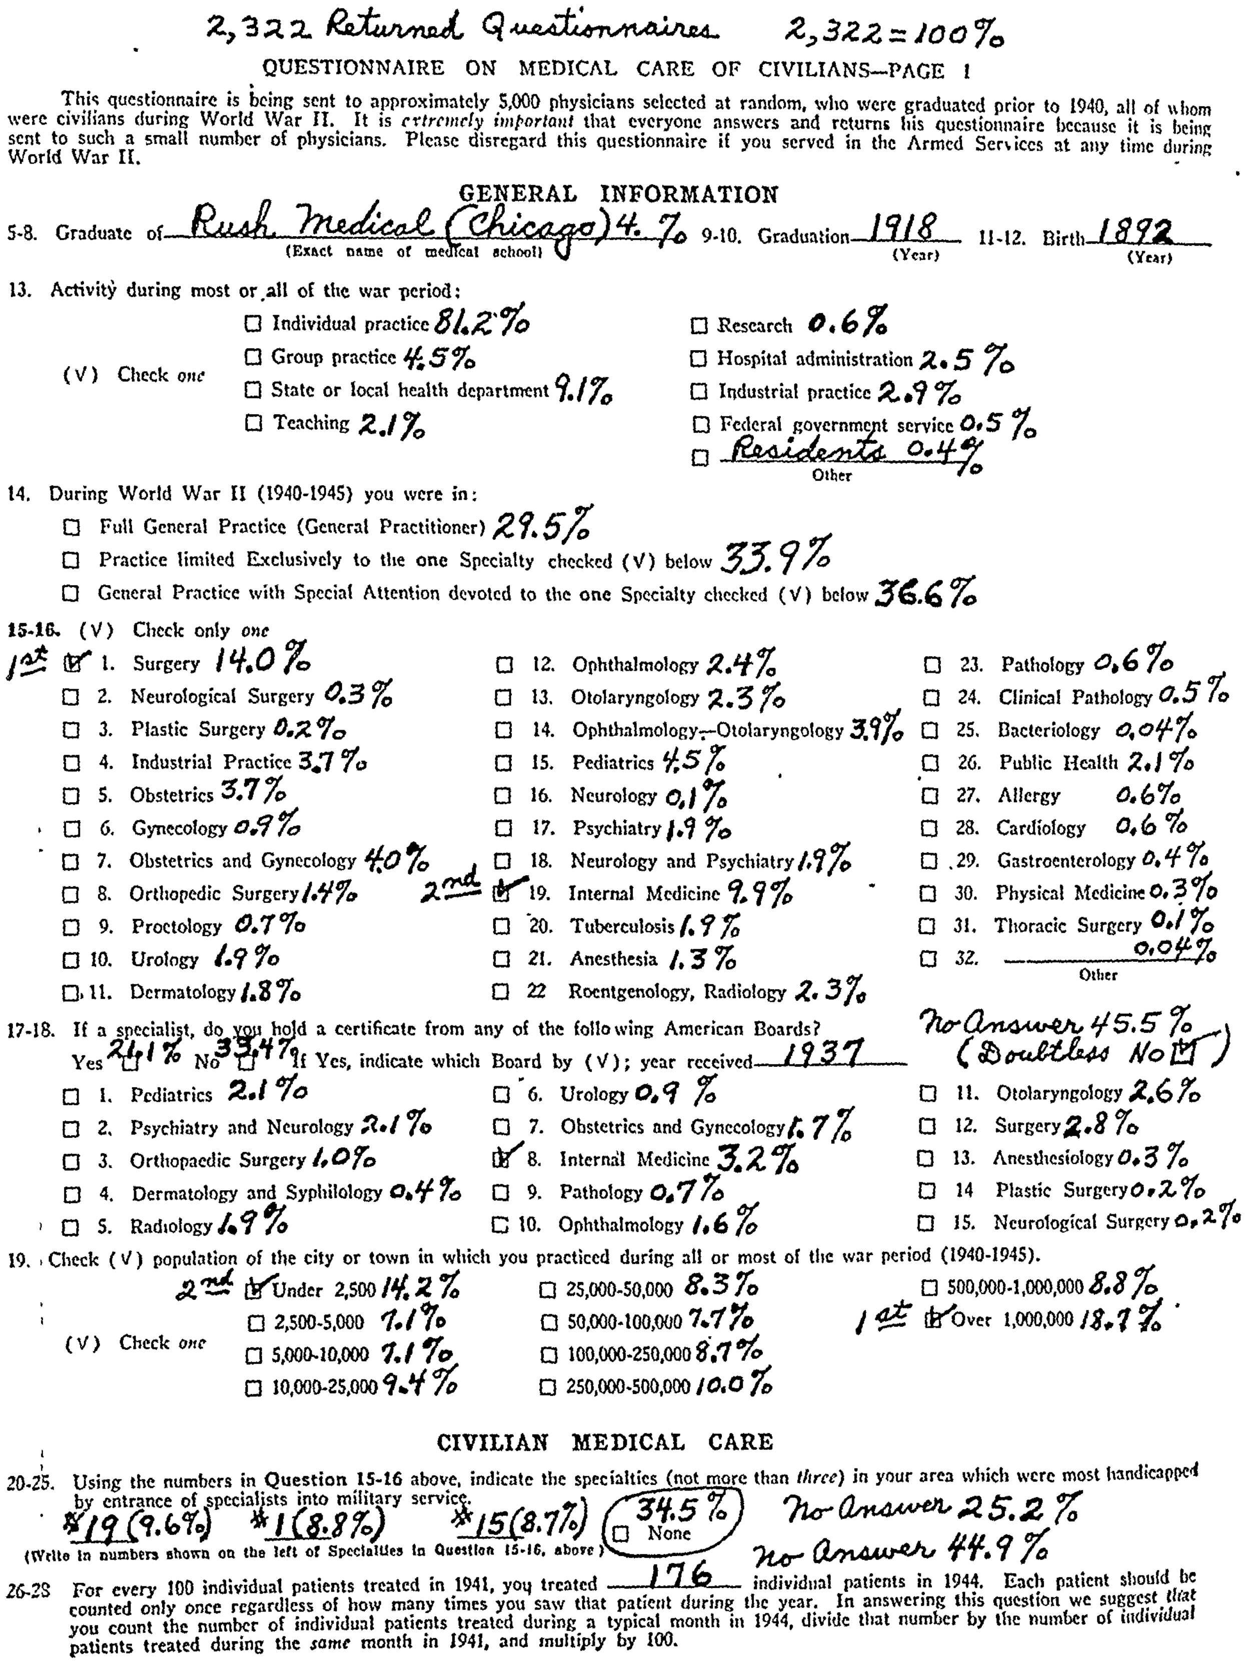
TABLE 1.—*Medical Schools from Which Doctors Graduated*

	Number	Per Cent of 2,322
1. Rush Medical College	92	4.0
University of Chicago	6	
	98	
2. University of Pennsylvania	76	3.3
3. Harvard Medical School	74	3.2
4. Columbia University College of Physicians and Surgeons	74	3.2
5 Jefferson Medical College	70	3.0
6 University of Minnesota Medical School	67	2.9
7. Northwestern University Medical School	57	2.5
8 University of Illinois College of Medicine	56	2.4
9. Johns Hopkins University School of Medicine	56	2.4
10 University of Michigan Medical School	54	2.3

Of the replying doctors in question 13, 81.2 per cent indicated that they were in individual practice during most or all of the war period, as shown in the facsimile. It was assumed that the overwhelming proportion of these doctors were in individual practice, so 81.2 per cent is not surprising. The number in group practice was rather high, 4.5 per cent, but I think that was due to interpretations of the question Doubtless two doctors in a partnership might have checked group practice, whereas the definition of group practice used by the Bureau requires at least three physicians as the minimum number for a group. Our punch card records have not been kept up to date; no comparisons of these percentages with the expected percentage for each activity could be made.

---

[1] The records permit reliable comparisons between the replies and the total number of doctors contacted only on the name of medical school, year of graduation and year of birth In other words, comparison can be made of the doctors who replied to this questionnaire with the doctors to whom it was sent on these three categories Of the ten medical schools from which the largest numbers of doctors of the 4,900 contacted graduated, nine of them were included in the first ten schools from which the 2,322 replying doctors graduated Therefore, on the basis of medical schools, the replies were representative of the entire random sample (4,900). The typical replying doctor graduated from medical school in 1918, whereas the typical doctor contacted graduated in 1916 This difference of two years introduces a bias which does not damage the results Contrariwise, it suggests that the replying doctors are a better sample of all civilian physicians in active practice than is the entire group of 4,900, many of whom are older and were not in active practice during the war. And that is precisely what the Reference Committee on Dec 10, 1946 wanted—a sample of those in active practice, not a sample of all M D's The percentage of replies from each state closely corresponds to the percentage of the national total of physicians in active practice in 1946, located in the state. The number of unusable questionnaires from retired physicians supports this statement. Something of the same situation exists regarding the year of birth The typical replying doctor was born in 1892, but the typical doctor in the random sample of 4,900 was born in 1889. Again this discrepancy suggests that the replying doctors are more representative of the physicians in active civilian practice during the war than the entire 4,900 contacted



2,322 Returned Questionnaires 2,322 = 100%

QUESTIONNAIRE ON MEDICAL CARE OF CIVILIANS—PAGE 1

This questionnaire is being sent to approximately 5,000 physicians selected at random, who were graduated prior to 1940, all of whom were civilians during World War II. It is *extremely important* that everyone answers and returns his questionnaire because it is being sent to such a small number of physicians. Please disregard this questionnaire if you served in the Armed Services at any time during World War II.

GENERAL INFORMATION

5-8. Graduate of Rush Medical (Chicago) 4.7% (Exact name of medical school) 9-10. Graduation 1918 (Year) 11-12. Birth 1892 (Year)

13. Activity during most or all of the war period:

(V) Check *one*

☐ Individual practice 81.2%
☐ Group practice 4.5%
☐ State or local health department 9.1%
☐ Teaching 2.1%
☐ Research 0.6%
☐ Hospital administration 2.5%
☐ Industrial practice 2.9%
☐ Federal government service 0.5%
☐ Residents 0.4% (Other)

14. During World War II (1940-1945) you were in:

☐ Full General Practice (General Practitioner) 29.5%
☐ Practice limited Exclusively to the one Specialty checked (V) below 33.9%
☐ General Practice with Special Attention devoted to the one Specialty checked (V) below 36.6%

15-16. (V) Check only *one*

1st ☑ 1. Surgery 14.0%
☐ 2. Neurological Surgery 0.3%
☐ 3. Plastic Surgery 0.2%
☐ 4. Industrial Practice 3.7%
☐ 5. Obstetrics 3.7%
☐ 6. Gynecology 0.9%
☐ 7. Obstetrics and Gynecology 4.0%
☐ 8. Orthopedic Surgery 1.4%

☐ 10. Ophthalmology 1.6%
☐ 11. Otolaryngology 2.6%
☐ 12. Surgery 2.8%
☐ 13. Anesthesiology 0.3%
☐ 14 Plastic Surgery 0.2%
☐ 15. Neurological Surgery 0.2%

19. Check (V) population of the city or town in which you practiced during all or most of the war period (1940-1945).

(V) Check *one*

2nd ☑ Under 2,500 14.2%
☐ 2,500-5,000 7.1%
☐ 5,000-10,000 7.1%
☐ 10,000-25,000 9.4%
☐ 25,000-50,000 8.3%
☐ 50,000-100,000 7.7%
☐ 100,000-250,000 8.7%
☐ 250,000-500,000 10.0%
☐ 500,000-1,000,000 8.8%
1st ☑ Over 1,000,000 18.7%

CIVILIAN MEDICAL CARE

20-25. Using the numbers in **Question 15-16** above, indicate the specialties (not more than *three*) in your area which were most handicapped by entrance of specialists into military service.

#19 (9.6%) #1 (8.8%) #15 (8.7%) 34.5% ☐ None No Answer 25.2%
(Write in numbers shown on the left of Specialties in Question 15-16, above)

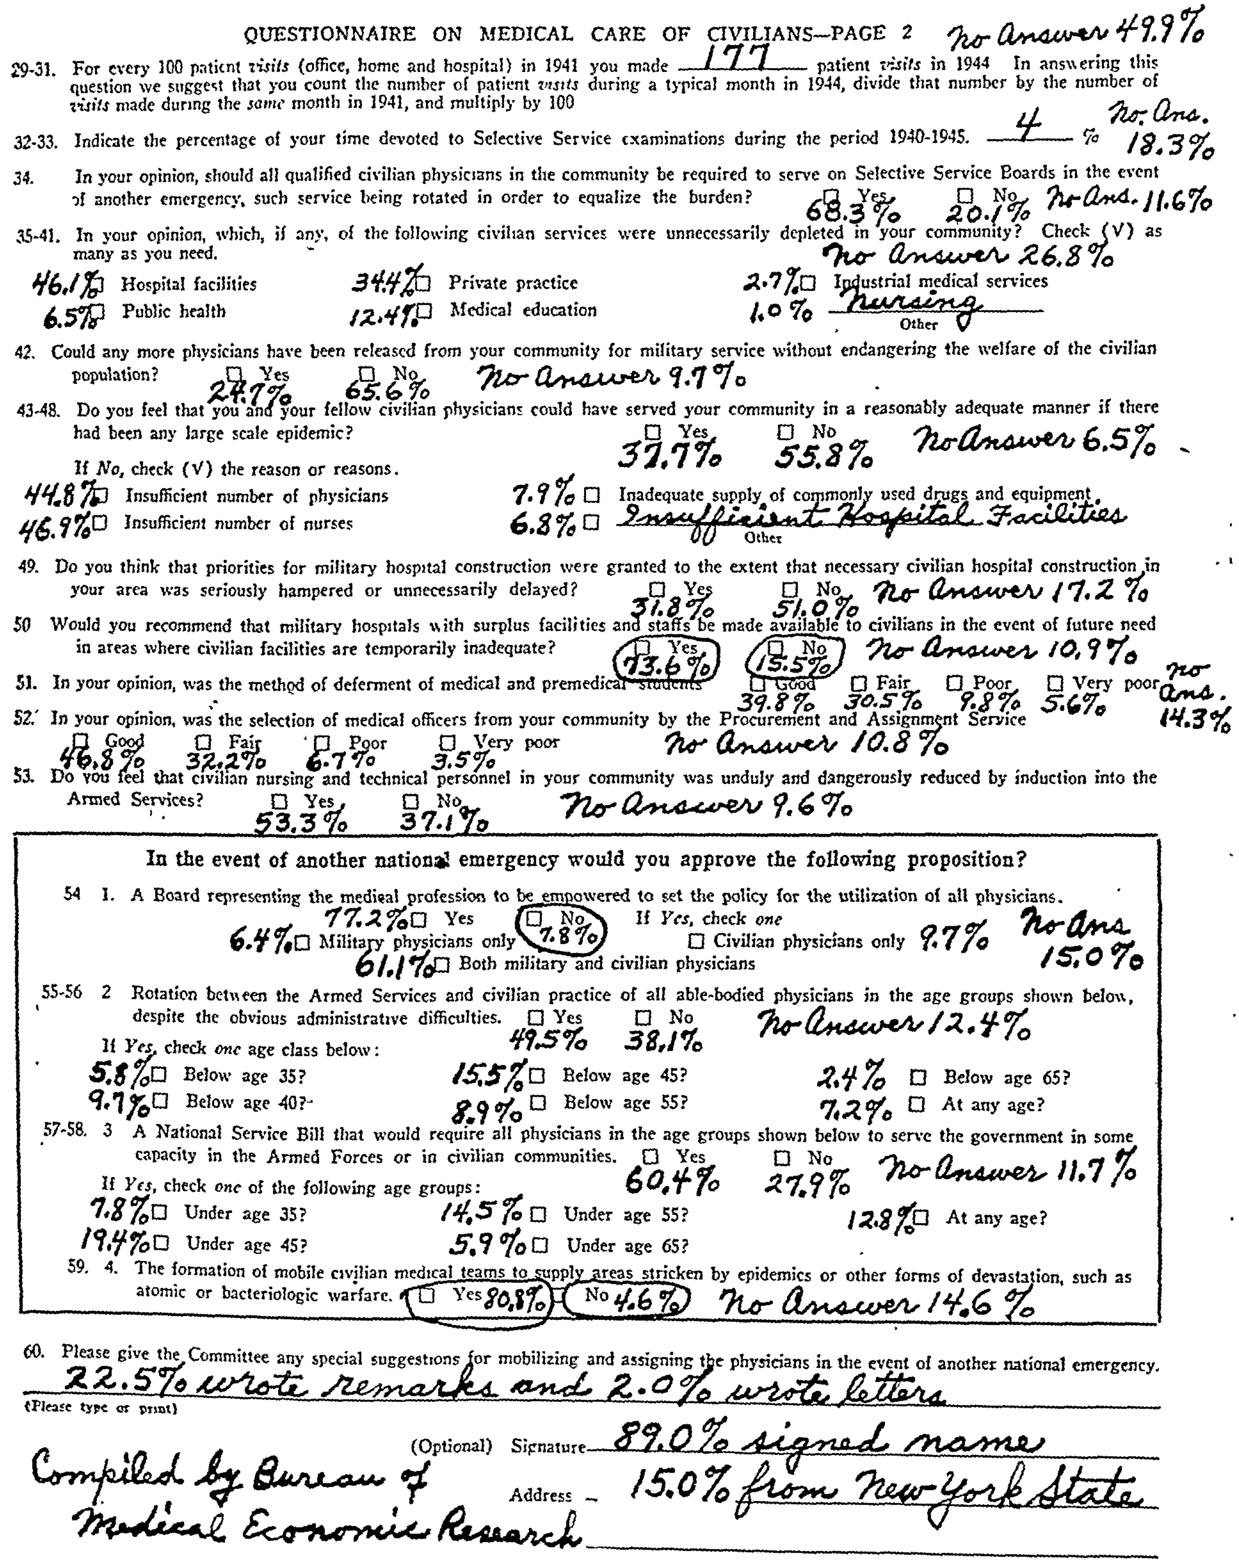
No Answer 44.9%

26-28 For every 100 individual patients treated in 1941, you treated 176 individual patients in 1944. Each patient should be counted only once regardless of how many times you saw that patient during the year. In answering this question we suggest that you count the number of individual patients treated during a typical month in 1944, divide that number by the number of individual patients treated during the *same* month in 1941, and multiply by 100.

In question 14, 29.5 per cent reported that they were in full general practice (general practitioners), 33.9 per cent reported that they were in practice limited to the one specialty checked (full time specialists), and 36.6 per cent reported that they had been in general practice with special attention devoted to the one specialty checked (part time specialists). The distribution here is remarkably even. The general practitioners plus the part time specialists constituted, therefore, 66.1 per cent of the replying doctors

Question 15-16 lists thirty-one specialties and asks the full time and part time specialists answering question 14 to check one of these thirty-one specialties. Fourteen per cent checked surgery and 9.9 per cent checked internal medicine. The percentages of replying doctors who checked each of these thirty-one specialties are shown in the facsimile on page 370. The reader is advised to ignore the smaller percentages, because 2,322 cards less those in full general practice (685) are insufficient for distribution into thirty-one specialties, particularly those specialties which few doctors checked.

In question 17-18 the replying doctor was asked to state whether he was a member of one of the fifteen American boards and to check the board; 21.1 per cent replied that they were members of American boards. The typical reply stated that the American board certificate had been received in 1937. It should be noted that 45.5 per cent did not answer this question. Most of the No Answers probably were No and the percentage of No Answers should be added to the percentage who checked No; 33.4 per cent checked No. The percentages for internal medicine and surgery are slightly higher than for any others.



QUESTIONNAIRE ON MEDICAL CARE OF CIVILIANS—PAGE 2 No Answer 49.9%

29-31. For every 100 patient *visits* (office, home and hospital) in 1941 you made 177 patient *visits* in 1944 In answering this question we suggest that you count the number of patient *visits* during a typical month in 1944, divide that number by the number of *visits* made during the *same* month in 1941, and multiply by 100

32-33. Indicate the percentage of your time devoted to Selective Service examinations during the period 1940-1945. 4 % No. Ans. 18.3%

34. In your opinion, should all qualified civilian physicians in the community be required to serve on Selective Service Boards in the event of another emergency, such service being rotated in order to equalize the burden? ☐ Yes 68.3% ☐ No 20.1% No Ans. 11.6%

35-41. In your opinion, which, if any, of the following civilian services were unnecessarily depleted in your community? Check (√) as many as you need. No Answer 26.8%

46.1% ☐ Hospital facilities
6.5% ☐ Public health
34.4% ☐ Private practice
12.4% ☐ Medical education
2.7% ☐ Industrial medical services
1.0% Nursing Other

42. Could any more physicians have been released from your community for military service without endangering the welfare of the civilian population? ☐ Yes 24.7% ☐ No 65.6% No Answer 9.7%

43-48. Do you feel that you and your fellow civilian physicians could have served your community in a reasonably adequate manner if there had been any large scale epidemic? ☐ Yes 37.7% ☐ No 55.8% No Answer 6.5%

If *No*, check (√) the reason or reasons.

44.8% ☐ Insufficient number of physicians
46.9% ☐ Insufficient number of nurses
7.9% ☐ Inadequate supply of commonly used drugs and equipment
6.8% ☐ Insufficient Hospital Facilities Other

49. Do you think that priorities for military hospital construction were granted to the extent that necessary civilian hospital construction in your area was seriously hampered or unnecessarily delayed? ☐ Yes 31.8% ☐ No 51.0% No Answer 17.2%

50 Would you recommend that military hospitals with surplus facilities and staffs be made available to civilians in the event of future need in areas where civilian facilities are temporarily inadequate? ☐ Yes 73.6% ☐ No 15.5% No Answer 10.9%

51. In your opinion, was the method of deferment of medical and premedical students ☐ Good 39.8% ☐ Fair 30.5% ☐ Poor 9.8% ☐ Very poor 5.6% no Ans. 14.3%

52. In your opinion, was the selection of medical officers from your community by the Procurement and Assignment Service ☐ Good 46.8% ☐ Fair 32.2% ☐ Poor 6.7% ☐ Very poor 3.5% No Answer 10.8%

53. Do you feel that civilian nursing and technical personnel in your community was unduly and dangerously reduced by induction into the Armed Services? ☐ Yes 53.3% ☐ No 37.1% No Answer 9.6%

In the event of another national emergency would you approve the following proposition?

54 1. A Board representing the medical profession to be empowered to set the policy for the utilization of all physicians. 77.2% ☐ Yes ☐ No 7.8% If *Yes*, check *one*
6.4% ☐ Military physicians only
☐ Civilian physicians only 9.7%
61.1% ☐ Both military and civilian physicians
No Ans 15.0%

55-56 2 Rotation between the Armed Services and civilian practice of all able-bodied physicians in the age groups shown below, despite the obvious administrative difficulties. ☐ Yes 49.5% ☐ No 38.1% No Answer 12.4%

If *Yes*, check *one* age class below:
5.8% ☐ Below age 35?
9.7% ☐ Below age 40?
15.5% ☐ Below age 45?
8.9% ☐ Below age 55?
2.4% ☐ Below age 65?
7.2% ☐ At any age?

57-58. 3 A National Service Bill that would require all physicians in the age groups shown below to serve the government in some capacity in the Armed Forces or in civilian communities. ☐ Yes 60.4% ☐ No 27.9% No Answer 11.7%

If *Yes*, check *one* of the following age groups:
7.8% ☐ Under age 35?
19.4% ☐ Under age 45?
14.5% ☐ Under age 55?
5.9% ☐ Under age 65?
12.8% ☐ At any age?

59. 4. The formation of mobile civilian medical teams to supply areas stricken by epidemics or other forms of devastation, such as atomic or bacteriologic warfare. ☐ Yes 80.8% ☐ No 4.6% No Answer 14.6%

60. Please give the Committee any special suggestions for mobilizing and assigning the physicians in the event of another national emergency.

Compiled by Bureau of Medical Economic Research

In question 19 the replying doctor was asked to check the size of the city in which he practiced during most or all of the war period. There are two open-end classes, namely under 2,500 and over 1,000,000. Naturally these two open-end classes would be expected to record the largest number of doctors. At the upper extreme is 18.7 per cent and at the lower extreme 14.2 per cent of the replying doctors. It is interesting to note that no replying doctor passed up this question.

THE SECOND PART OF THE QUESTIONNAIRE

After the discussion of the composite replies to each question, a summary in footnote style at the end of the paragraph sets forth what group of replying doctors checked considerably more than their proportionate and considerably less than their proportionate number of Yes, No, No Answer, and so on. This device avoids printing approximately 150 tables developed by running the punch cards through the machines several times. If the replies were proportionate or the group of replying doctors was too small for comparisons, no comment (indicated by —) is offered. This procedure focuses attention on the unusual responses to each question. It serves to answer "Who wrote what?" And the fewer the comments, the more agreement there was among the different replying doctors on the Yes, No, No Answer, and so on. The abbreviations used are:

Question 13.—Individual practice, IPr; group practice, GrP; state and local health departments, SLHD.

Question 14.—Full general practice, GP; full time specialist, FTS; part time specialist, PTS.

Question 15-16.—One word, first three letters; two words, first three letters of each word.

Question 17-18.—Same as 15-16 but with prefix of "Bd"; non-board members, nonBd.

Question 19.—No abbreviations needed but "cities of" is omitted.

The first question in the second section of the questionnaire is 20-25, in which the doctor was asked to indicate the specialties in his area which were most handicapped by entrance of specialists into military service, using the numbers of the thirty-one specialties listed in question 15-16. The most depleted specialties were 19, 1 and 15, internal medicine, surgery and pediatrics. Of the replying doctors 34.5 per cent stated that there was no specialty which was especially depleted by entrance of specialists into the military service; 25.2 per cent gave No Answer.

Question 20-25 Specialty Mentioned	More than Proportionate	Less than Proportionate
1. No answer.......	GP	IPr
2. None............	IPr	FTS
3. Surgery.........	FTS	GP, PTS, age 70-74
4. Pediatrics.......	IPr, FTS, 50,000 to 250,000, ages 35-39 and 45-49	GP, age 65-74
5. Internal Medicine	FTS	IPr, GP, under 2,500

Question 26-28 was designed to indicate the increase in the patient load of these replying physicians who maintained civilian practice during the war period. The doctor was asked to state the number of patients treated in 1944 for every hundred patients treated in 1941. The mean or average of the replies was 176. This implies that the doctor treated 76 per cent more patients in 1944 than in 1941. The high percentage of No Answer; 44.9, indicates the difficulties involved in answering the question. The first question on the top of the second page is quite similar. This question, 29-31, required the replying doctor to indicate the increase in the number of patient visits rather than in the number of patients. The mean or average was 177, and No Answers constituted 49.9 per cent. This indicates that one half of the replying doctors in civilian practice reported 77 per cent more patient visits in 1944 than in 1941. The exact percentage increase for all civilian doctors may not be too clearly defined because of the wording of the question and the large percentage of No Answer. Nevertheless it strongly suggests that the typical civilian doctor was called on during this period to see approximately three fourths more patients in 1944 than in 1941.

Question 26-28	More than Average Increase	Less than Average Increase
	GrP, PTS, 2,500 to 25,000, 50,000 to 100,000, BdRad, BdObs&Gyn, BdSur, age 30-39	GP, 25,000 to 50,000, over 500,000, BdOto, age 65-74

Question 29-31	More than Average Increase	Less than Average Increase
	GrP, PTS, 2,500 to 25,000, 50,000 to 100,000, 250,000 to 500,000, BdPed, BdOrtSur, BdUro, BdSur, age 30-44	GP, 25,000 to 50,000, over 500,000, BdPsy&Neu, BdOto, BdRad, ages 45-49 and 60-74

The replies to these two questions provide a significant economic commentary on the practice of medicine by civilian doctors during the war. I do not believe that it means that the work week of the civilian doctor during this period was increased from, let us say, forty-four hours to seventy-seven hours. Probably the doctor treated more patients per hour. It presents an economic rationalization of the increase in the average income of physicians during the war period. If the volume of practice they did during the war period increased by three fourths, an increase in income by approximately the same ratio indicates no changes in fee scales. It must be remembered that something more than 40 per cent of the practicing physicians were taken into military service, leaving 60 per cent or less of the practicing physicians to take care of the 91 per cent of the population which remained civilian. On this basis alone one would have expected an increase of at least one half in the patient load of the average physician in civilian practice. It is also likely that the increase in the purchasing power of the people induced them to call on doctors more frequently than they had been accustomed to in less prosperous times. So rule-of-thumb national averages seem to warrant a conclusion that the increase in the patient load must have been at least two thirds. I cannot avoid asking the question: How many other people in civilian life were called on to carry a load three fourths greater than in peacetime?[2]

Question 32-33 asked the doctor to indicate the percentage of his time devoted to Selective Service Board examinations during the war period. The typical reply was 4 per cent, although the number of doctors who failed to answer was 18.3 per cent. This percentage of 18.3 per cent No Answer can be counted as zero or can be excluded; it makes a difference of only a fraction of 1 per cent, so that the typical reply is still that 4 per cent of the doctor's time was devoted to Selective Service Board examinations.

Question 32-33	More than Four Per Cent	Less than Four Per Cent
	SLHD, over 1,000,000, age 65-69	GrP

In question 34 the doctor was asked to express an opinion as to whether all qualified civilian physicians in his community should be required to serve on Selective Service Boards in the event of another national emergency with such service being rotated in order to equalize the burden—a fair question; and the response was clear, 68.3 per cent of the doctors answering Yes, 20.1 per cent answering No and 11.6 per cent giving No Answer. This indicates that at least two thirds of the doctors believe that in the event of another national emergency all qualified civilian physicians should be required to serve on Selective Service Boards, such service being rotated in order to equalize the burden.

Question 34 Reply	More than Proportionate	Less than Proportionate
1. Yes.............	——	——
2. No..............	——	——
3. No answer......	GP, under 2,500, non-Bd, BdPsy&Neu, BdOph, age 65-74	IPr, over 1,000,000, Bd, BdIntMed, age 40-44

In question 35-41 the doctor was asked to state his opinion as to which of the listed civilian services were unnecessarily depleted in his community; 46.1 per cent checked hospital facilities as being unnecessarily depleted, 34.4 per cent checked private practice, 12.4 per cent checked medical education, 6.5 per cent checked public health, 2.7 per cent checked industrial medicine and 1 per cent wrote Nursing in the blank for Other. The fact that 1 per cent wrote in Nursing should rate it much higher than 1 per cent, because Nursing was not printed as an item to be checked.

---

[2] Some day when the Bureau completes its study of the number and causes of deaths of physicians during this war period and converts the data into the form of a mortality table, there may be even clearer evidence of the tremendous load carried by the civilian doctor in wartime.

Question 35-41 Reply	More than Proportionate	Less than Proportionate
35. Hosp. Facil....	Over 1,000,000	GP
36. Pub. Health....	SLHD, nonBd, BdPsy &Neu, BdOrtSur, BdRad	IPr, FTS, Bd, age 60-64
37. Private Pr.....	———	———
38. Med. Educ......	FTS, over 1,000,000, Bd	IPr, GP, PTS, nonBd
39. Indus. Med. Serv.	2,500 to 5,000	IPr, 10,000 to 25,000
40. Nursing........	IPr, 50,000 to 100,000, over 1,000,000, age 30-39	Age 40-44 and 60-64

Question 42 was probably the most important single question in this questionnaire. It is, in fact, the key question on the two questionnaires taken together. It asked this random sample of civilian physicians point blank if more physicians could have been released from their communities for military service without endangering the welfare of the civilian population; 24.7 per cent wrote Yes and 65.6 per cent No; 9.7 per cent passed up the question without answering it. In the opinion of the physicians who remained at home, too many physicians were removed from civilian practice from the standpoint of community welfare. This, of course, does not fully answer the question of military necessity.

Question 42 Reply	More than Proportionate	Less than Proportionate
1. Yes..............	IPr, over 1,000,000, age 50-54	Under 2,500
2. No...............	Under 2,500	———
3. No answer.......	FTS, over 1,000,000, BdIntMed, age 35-39 and 50-79	PTS, BdOto

In question 43-48 the doctor was asked whether he felt that he and his fellow physicians could have served his community in a reasonably adequate manner if there had been a large scale epidemic; fortunately none occurred. Six and five-tenths per cent of the doctors passed up this question, 55.8 per cent checked No and 37.7 per cent checked Yes. If the doctor answered No he was asked to check the reason or reasons for his statement. Of the 55.8 per cent who checked No 44.8 per cent, or about four fifths, gave as one reason the insufficient number of physicians. A slightly larger number, 46.9 per cent, gave an insufficient number of nurses as the reason. A much smaller percentage, 7.9, gave inadequate supply of commonly used drugs and equipment. A blank space was provided for them to write in other reasons; it is significant that 6.8 per cent wrote in Insufficient Hospital Facilities.

Question 43-48 Reply	*More than Proportionate*	*Less than Proportionate*
43. Yes..................	———	———
43. No...................	———	———
(a) Insufficient Phys.	———	Over 1,000,000
(b) Insufficient Nurses	———	———
(c) Insufficient Drugs	BdUro, BdSur	BdIntMed
(d) Hosp. Facilities..	100,000 to 250,000, 500,000 to 1,000,000, Bd, BdSur	Under 2,500, over 1,000,000, nonBd, BdPsy&Neu
43. No answer...........	GP, over 1,000,000, BdPsy&Neu, BdOph, age 75-79	IPr, PTS, BdInt Med, age 50-54

In question 49 the doctor was asked to express an informed opinion as to whether the priorities for military hospital construction were granted to such an extent that necessary civilian hospital construction in his area was seriously hampered or unnecessarily delayed. Here 17.2 per cent failed to answer the question; 51 per cent replied No and 31.8 per cent Yes. I interpret this response to mean that the doctors felt that military hospital construction was reasonably well handled from the standpoint of civilian medical care, although it interfered with their civilian programs.

Question 49 Reply	More than Proportionate.	Less than Proportionate
1. Yes.............	BdSur	GP
2. No..............	IPr	———
3. No answer.......	FTS	PTS

Question 50 is allied to question 49. The doctor was asked whether he would recommend that military hospitals with surplus facilities and staffs be made available to civilians in the event of future need in areas where civilian facilities were temporarily inadequate. The reply to this question was 73.6 per cent Yes and 15.5 per cent No; 10.9 per cent did not answer the question. The replies indicate that the great majority of civilian doctors felt that in trying to take care of their civilian communities during World War II the local military hospitals, which were overstaffed and had many idle beds, should have been opened up to civilians.

Question 50 Reply	More than Proportionate	Less than Proportionate
1. Yes.............	———	———
2. No..............	IPr	BdPed, BdPsy&Neu
3. No answer.......	Age 75-79	PTS, BdPed

In the next question they were asked to rate the method of deferment of medical and premedical students. Here 39.8 per cent checked Good, 30.5 per cent Fair, 9.8 per cent Poor and 5.6 per cent Very Poor; 14.3 per cent did not answer the question. I interpret this to mean that the civilian doctors were, on the whole, rather well satisfied with the deferment of medical and premedical students. At least it certainly implies no severe criticism of the procedures and practices of those in authority.

Question 51 Reply	More than Proportionate	Less than Proportionate
1. Good............	———	———
2. Fair.............	———	———
3. Poor............	PTS, BdIntMed, BdSur	GP
4. Very poor.......	FTS, Bd, BdRad, age 50-54	NonBd, BdIntMed
5. No answer.......	GP, nonBd, age 70-79	PTS, Bd, age 50-54

In question 52 the doctor was asked to express his opinion regarding the selection of medical officers from his community by the Procurement and Assignment Service. Here again one finds what was on the whole a favorable reply, since 46.8 per cent checked Good, 32.2 per cent Fair, 6.7 per cent Poor and 3.5 per cent Very Poor; 10.8 per cent did not answer this question. It would be fair to conclude that the civilian practitioner was rather favorably impressed with the work of Procurement and Assignment.

Question 52 Reply	More than Proportionate	Less than Proportionate
1. Good............	———	———
2. Fair.............	———	———
3. Poor............	25,000 to 50,000, BdPat, BdSur	BdIntMed, BdOto
4. Very poor.......	IPr, PTS, 10,000 to 25,000, nonBd, BdPsy &Neu, BdRad, BdObs&Gyn	FTS, Bd
5. No answer.......	GP, under 2,500, nonBd, BdOph, age 70-79	FTS, Bd, age 50-54

Question 53 asked the doctor to appraise the availability of civilian nursing and technical personnel in his community as to whether it was unduly and dangerously reduced by induction into the armed services: 53.3 per cent checked Yes, 37.1 per cent No and 9.6 per cent passed up this question without answering it.

Question 53 Reply	More than Proportionate	Less than Proportionate
1. Yes.............	———	———
2. No..............	———	FTS
3. No answer.......	GP, BdPat, age 75-79	PTS, BdObs&Gyn

THE FOUR PROPOSITIONS

Now come four important propositions on which the civilian doctor was asked to vote. Question 54, proposition 1, asked the doctor if he would favor, in the event of another national emergency, a board representing the medical profession to be empowered to set the policy for the utilization of all physicians, to which 15 per cent of the doctors did not reply; but only 7.8

per cent checked No, and 77.2 per cent checked Yes; 6.4 per cent indicated that this board should set the policy for the utilization of military physicians only, 9.7 per cent indicated that this board should set the policy for civilian physicians only but 61.1 per cent, the overwhelming majority (four fifths of the Yes checks), said that this board should set the policy for the utilization of both military and civilian physicians. Evidently the civilian doctor believes that a board representing the medical profession itself should be empowered to set the policy for the utilization of all physicians in the event of another national emergency.

Question 54	More than Proportionate	Less than Proportionate
Reply		
1. Yes....................	——	——
1a. Military Phys. only	IPr, GP, age 40 44	FTS
1b. Civilian Phys. only	IPr, age 60-64	——
1c. Both..	——	——
2. No....................	PTS, nonBd	Bd
3. No answer............	GP	——

Proposition 2, that is, question 55-56, asked the doctor whether he believed that rotation between the armed services and civilian practice of all able bodied physicians in the age groups shown below should, despite the obvious administrative difficulties, be required. This question was passed up by 12.4 per cent of the doctors; 38.1 per cent checked No and 49.5 per cent checked Yes. Apparently the replying doctors are not appalled by obvious administrative difficulties or they think the next war will be quite different; 15.5 per cent checked Yes provided it was for physicians below age 45, 9.7 per cent specified below age 40 and 8.9 per cent specified below age 55, and so on.

Question 55-56	More than Proportionate	Less than Proportionate
Reply		
1. Yes..............	——	——
1a. Under age 35	Under 2,500, age 30-34	FTS, 250,000 to 500,000, age 55-59
1b. Under age 40	Age 35 39	——
1c. Under age 45	——	——
1d. Under age 55	Age 50-54	——
1e. At any age..	——	FTS, age 50-54
2. No...... .. .	——	——
3. No answer.......	Age 70-79	Age 40-44 and 50-54

Proposition 3 invited the doctor to vote on the question of whether he would favor a national service bill that would require all physicians to serve the government in some capacity in the armed forces or in civilian communities; 11.7 per cent passed up this question without reply, 27.9 per cent checked No and 60.4 per cent checked Yes. Those who checked Yes were asked to specify the age group to which this national service bill should apply; 19.4 per cent specified under age 45, 14.5 per cent specified under age 55 and 12.8 per cent specified at any age. It seems to me that proposition 3 might possibly have secured a majority vote of 60.4 per cent because the replying doctor read it in connection with proposition 1, on which he had already voted. Of those who approved 1, 67 per cent also checked Yes on 3, 28 per cent checked No and 5 per cent passed up 3. I do not know how much weight should be given to this consideration, but I believe that a separate interpretation of proposition 3 while ignoring proposition 1 might provide some rather questionable conclusions. The four propositions were enclosed in a box. The replying doctor may have been thinking in terms of a national service bill with a board representing the medical profession being empowered to set the policy for the utilization of all physicians. I cannot really determine just what the score is on this point, but I do conclude in general from the answers to question 3 that civilian doctors do think that there should be a national service bill of some sort in the event of another national emergency and that all physicians of a reasonable age should be required to serve the government in some capacity and that this board, representing the medical profession, should be empowered to set the policy for the utilization of all physicians. It is a question for the Committee to determine just how strong an interpretation it will want to place on these two propositions, 1 and 3, separately or combined.

Question 57-58	More than Proportionate	Less than Proportionate
Reply		
1. Yes..............	——	——
1a. Under age 35	——	——
1b. Under age 45	——	——
1c. Under age 55	——	GP
1d. Under age 65	Age 60 64	——
1e. At and age..	——	Age 50 54
2. No..............	——	——
3. No answer.......	Age 70 79	——

In the last of the four propositions the physician was asked to cast a vote on the question of the formation of mobile civilian medical teams to supply areas stricken by epidemics or other forms of devastation such as atomic or bacteriologic warfare. Although 14.6 per cent passed up this question, it is most significant that only 4.6 per cent checked No and 80.8 per cent Yes. A much stronger question than this might have been asked, but in the framing of questionnaires it is always desirable to avoid what statisticians like to call a leading question. It seems clear that if 81 per cent of the doctors are willing to support the formation of mobile civilian medical teams they are certainly aware that in the next war the task of taking care of civilians "after the storm" may be a greater medical problem than the medical care of military personnel. The vote on this question clearly indicates that the civilian doctors of America are aware of the serious implication of possible atomic and bacteriologic warfare.

Question 59	More than Proportionate	Less than Proportionate
Reply		
1. Yes..............	——	——
2. No..............	PTS, 25,000 to 50,000, nonBd	FTS, over 1,000,000, Bd
3. No answer.......	Age 70-79	——

The last question, 60, merely called for special comments. Replies were received from 523, 22.5 per cent of replying doctors. The number of letters attached was 2 per cent of the number of replies, although no letter was requested; 15.0 per cent of the replying doctors were from the state of New York, and 89 per cent of the replying doctors signed their names to their questionnaire.

A SUPPLY RIDDLE

The combined results of the two questionnaires pose a riddle. More doctors than necessary in the opinion of 26,000 discharged medical officers were inducted into military service and too few remained at home in the opinion of the doctors in the random sample. Yet the general health of civilians (and of military personnel) was at an all time high. This coincidence may cast doubts on the claim that the nation is suffering from a serious shortage of doctors; that is, inadequate to maintain our unequaled rate of health progress. The full effects of complete demobilization of doctors will not be felt until late 1948, because so many discharged doctors (perhaps 20,000) chose to pursue graduate training before going into active practice. How much lower would the general death rate among civilians have fallen *with an adequate supply of civilian doctors not working overtime*, aided by the full impact of the new drugs, war plant industrial medicine, helpful food and gas rationing, and the healthy participation of citizens in wartime activities which made them impervious to diseases caused by self pity?

The exact percentages shown for the replies to each question can be forgotten. The overall results of the replies to the second questionnaire from a random sample of civilian physicians present a challenge to organized medicine to initiate now a well rounded, wise and carefully prepared program designed to provide for quick mobilization of our nation's medical resources preparatory to another national emergency.

JOINT COMMITTEE FOR THE COORDINATION OF MEDICAL ACTIVITIES

Report of Meeting in Chicago, February 22

The Joint Committee for the Coordination of Medical Activities met in the Board of Trustees Room of the American Medical Association Building in Chicago, Saturday, February 22, and was called to order by the Chairman, Dr. Ernest E. Irons, at 10:05 a. m. Members and guests present were:

Dr. Irvin Abell
Col. George E. Armstrong
Dr. Walter L. Bierring
Dr. W. Palmer Dearing
Dr. Warren F. Draper
Capt. William E. Eaton
Dr. Morris Fishbein
Dr. John H. Fitzgibbon
Dr. Evarts A. Graham
Dr. Johnson F. Hammond
Dr. E. L. Henderson
Dr. Hugo V. Hullerman
Dr. Ernest E. Irons
Dr. Edwin P. Jordan
Dr. George F. Lull
Dr. J. J. Moore
Dr. H. B. Mulholland
Dr. Carl M. Peterson
Lt. Col. William N. Piper
Dr. R. L. Sensenich
Dr. H. H. Shoulders
Dr. Leroy P. Sloan
Dr. Austin E. Smith
Miss Mary Switzer

SURPLUS PROPERTY

Miss Switzer, member of the Subcommittee on Surplus Medical and Hospital Supplies, reported that, pursuant to suggestions made at the January meeting, she had investigated the status of directive 23 issued by the War Assets Administration. She said it had been possible to get the directive reactivated within the authority under which it was originally issued until March 31, at which time many of the basic authorities of the Civilian Production Administration, including the one that is dealt with in directive 23, expire. Miss Switzer recommended that the subcommittee be discharged, and the Committee so voted.

GRADUATE EDUCATION OF PHYSICIAN VETERANS

Dr. Lull presented a question which had been propounded to him by a chief of staff of a hospital. This person had stated that only veterans were in training as residents, with tuition paid by the Veterans Administration, in that hospital, and that there is one vacancy for which no veteran is obtainable. He asked whether, if a well qualified nonveteran was appointed to this vacancy, it would cause the hospital to lose the tuition payments of the veteran residents. Dr. Lull said he had understood that tuition was paid to hospitals as a result of their making extra residencies available. Miss Switzer said such tuition was made available if it was demonstrated that the hospital had to increase its teaching staff to provide for the extra residencies and thereby was subjected to extra expense. The Chairman suggested that the inquirer be told to contact the local office of the Veterans Administration, and Dr. Hullerman thought that definite information could be obtained quickly through the Washington office of the American Hospital Association, which is keeping in close touch with these matters.

ARMY SPECIALIZED TRAINING PROGRAM AND WAR DEPARTMENT DEFERMENT POLICY

Dr. Shoulders read the following letter, which he said was representative of a number of communications he had received as President of the American Medical Association:

> Dear Dr. Shoulders:
>
> This letter is directed to you in the hope that some perplexing statements and situations may be clarified by being brought to the attention of some one who is interested and influential in the medical profession and the people concerned. The desire to correspond with you was given added impetus when it was realized that you do receive and acknowledge other letters similar in content to this. This was learned while reading the proceedings of the Committee on Postwar Medical Service, as published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Jan. 4, 1947. Reference was made to letters you had received from a certain group of physicians in the Navy.
>
> Whether or not you have received or will receive letters presenting the same material as this one, I, of course, am unable to state. Nevertheless, I am confident that the matter which I wish to present to you is in the minds of several thousand young physicians in the Army, recently separated from the services, as well as those expecting eventual call into the services. It is the subject matter of a great many conversations among us who are concerned. It appears appropriate, then, that these facts be brought to the American Medical Association, with which the vast majority of us have been affiliated in one way or another since we pursued medicine as a profession—and to which we look for policies, direction and aid in problems that confront us. It is with such an attitude that this letter is submitted for your consideration.
>
> Many of us now serving in the Army were deeply perplexed when we read in the Dec. 21, 1946 issue of THE JOURNAL that 1,500 of the current intern group would be deferred for from six to twelve months beyond the normal termination of their internships in order that they might continue in civilian hospitals as interns and residents. The reasons given for this action were (1) because of the "need of civilian hospitals for junior residents and/or interns" and (2) "the desirability of continuing the deferment of as many officers as possible so they might continue their training."
>
> Our perplexity stemmed from the impression that there is still a surplus of applicants from veteran physicians seeking residency training in civilian hospitals. We have seen many references to the splendid efforts of committees of the American Medical Association who are trying to solve the problem of great demand for such training. Most of us have friends who are waiting or searching for a hospital residency; knowing this, it is most difficult to understand wherein there could be any "need of civilian hospitals for junior residents." Similarly, by July 1, 1947 there will be a new group of medical graduates available for internships. This group should be of equal size to the present group of interns and could completely replace it as an intern group. Why, then, should there be any need for continuing any of the current group on an intern basis?
>
> Indeed, we do agree that it would be desirable for the present intern group to continue their training, but it can hardly be denied that others are more deserving of such an opportunity at this time, namely the veteran physicians and those who are currently in military service. In the latter two groups are physicians who have not had that opportunity as yet, even though they are older than those for whom further deferment is being permitted. It is pertinent to point out at this time that the group to be further deferred will automatically receive longer hospital service as interns than was permitted some veterans and practically all who are now in service. This was the result of conversion from the 9-9-9 program to the prewar twelve month internship. Because of this transition, a large portion of the present intern group will serve fifteen months as interns in contrast to the nine month period in effect during the war. Hence they will receive six months' more training as interns than did most of us who are now in service. Yet we are retained in service for a designated twenty-four months, while 1,500 interns eligible for service in the Army and who will automatically get six months' more internship than we did will be permitted a still longer immunity from military service, ranging from six to twelve months.
>
> Another source of contention is the fact that the current group of interns received the maximum benefits under the Army Specialized Training Program. They were the group who enjoyed free tuition, books, clothing, board and room, and a salary during the entire time that the program was in operation. This amounted to more than thirty months of the approximately thirty-six months required by most medical schools. Not only did this group receive the maximum financial benefits, they also received the maximum acceleration of their professional studies and are therefore relatively and actually younger than those of us now in service, and certainly they are younger than the veteran physicians with whom they will compete for civilian hospital training under the War Department directive to which reference is being made. Certainly no group is more obligated to military service than the present interns in view of the very considerable government sponsored benefits they have received. Likewise, no other group can serve in the military services with so few personal sacrifices, for they are younger, not in debt for their professional education, and automatically are receiving a longer internship than was permitted during the war. Does it not seem more desirable and just to permit others "to continue their training" rather than to prolong the length of service for those still in service, and to increase the difficulties some veteran physicians are encountering in obtaining residencies—while a favored group receives still greater benefits than those they already have been granted?
>
> At least one group was suitably organized and adequately incensed to register a complaint to the source of this policy. In the Jan. 18, 1947 issue of THE JOURNAL on page 184 is an item referring to the action of a group of physician veterans who were termed "Docvets." Their complaint dealt with only one aspect of the complete picture apparently. They protested to the Surgeons General of the Army and Navy that the positions in civilian hospitals should be filled by veteran physicians rather than those who have had so many other government benefits, who are already receiving a fifteen month internship and who have thus far had no military service. As reported in this article, "the Army Surgeon General explained that 3,000 medical school graduates whose

tuition was paid by the government are available for army service. The Army can't use them now, which is the reason for deferments." With this statement, a third reason for the deferment policy was given, and it is in no apparent way associated with the implications of the previously stated two reasons. While giving this revised reason for the deferment policy previously published, the same source commented that hospitals should employ veterans rather than younger doctors without military service. The latter statement is indeed commendable and was perhaps adequate to appease the "Docvets" who made the complaint. However, the composite of reasons and statements still leaves much to be desired by those who are at present in service and have been anxiously awaiting an announcement that some relief from the twenty-four month requirement of service might be forthcoming.

In the August 1946 Educational Number of THE JOURNAL is a numerical breakdown of all four classes in medical schools throughout the country. One statistical table shows there were 3,567 Army Specialized Training Program students in the senior class of the year 1945-1946. *This is the group now interning. This figure is incongruous* with the one used in reply to the "Docvets." One might reasonably ask what has become of more than 500 able bodied men who were in their senior year in medical school during 1945-1946? Likewise, one might ask why physicians who have received little or no medical education at government expense are retained in service for twenty-four months if a surplus does exist, as is indicated by the more recent statement regarding the justification of the deferment policy. Why can't physicians who had from none to twelve months A. S. T. P. training be replaced by those surplus, government educated, fifteen month interns? Or why couldn't they be used to replace physicians who were taken into the service with disqualifying defects and diseases? Not only does the latter group constitute a potential source of government claim for disability, but they also tend to increase the needs for greater medical care and hospitalization, to say nothing of their own physical and mental welfare while subjected to two years of military service. Surely if an overabundant supply of fully qualified physicians is available, it would be well to have them replace those physicians who are serving in spite of chronic diseases and disabling defects.

If the first two reasons given for the deferment policy are to be given credence, then it is suggested as a means of increasing the training periods of young physicians, a policy could be adopted whereby physicians now in the service would be relieved from active duty on presentation of evidence of having an approved residency appointment. After all, it is this group whose training was interrupted early by military service, and who are now older, and time for residency training is becoming increasingly short and valuable. Many have financial obligations dating back to their school years which were financed partially or wholly from private sources and not entirely by government programs. Then too, by this arrangement the too frequent long period of waiting for a residency to begin after separation from service would be obviated, thus eliminating a further waste of time, ability and knowledge. In this way the surplus of eligible young physicians could be utilized to replace those who were separated from service to avail themselves of a desired and earned opportunity for further hospital training in accredited civilian institutions. Such a program was in effect for selectees during the past fall, at which time they were discharged if they had proof of acceptance from a college. Could not the same privilege be extended to the professional man in service who is seeking advanced training and whose age makes his time at least equally if not more valuable than that of the recent high school graduate?

As a final suggestion for a more desirable alternative than the present policy, if an appreciable surplus of physicians exists who are eligible and undeniably obliged to military service, why can't the overall requirement of twenty-four months' service for physicians be reduced? Complaints are commonly heard from physicians in service who are not doing professional work or whose abilities have not been utilized in any capacity for appreciable periods of time. Add to these extravagances of professional talents an excess of available personnel, it is difficult to understand why two years of service remains the inflexible requirement. Certainly it would create better morale than the present policy of declaring a certain few doctors "surplus to the needs of the service" and discharging them, while others with precisely the same qualifications and same length of service are retained to fulfil the twenty-four month requirement.

It is my sincere hope, Dr. Shoulders, that you will give some consideration to the facts, impressions and suggestions offered in this letter. The content has been given much serious thought and is representative, I am confident, of the attitudes and bewilderment of a great portion of us who are now in service. A reply from you will be most welcome, and any information you may offer to clarify our position and our future will be most gratefully accepted.

In view of the fact that I am now in service and not desirous of provoking any retaliation on myself or my associates, it is my urgent request that my name be held in your confidence. I sincerely appreciate your indulgence and consideration.

Respectfully submitted,

Dr. Shoulders asked Colonel Armstrong, as chief of personnel in the Office of the Surgeon General of the Army, to give him some information on which he might base a satisfactory reply.

Colonel Armstrong replied at length and promised to send for publication a statement covering his remarks. That statement follows:

1. The Office of the Surgeon General, War Department, and the American Medical Association *have recently been in receipt of* numerous letters, indicating that confusion and misunderstanding exists at present regarding the current deferment policy for graduates of the Army Specialized Training Program now completing internships and who, unless deferred, will be called to active military service on or about 1 July 1947.

2. The Army Specialized Training Program was initiated in July 1943 in an effort to guarantee an adequate source of physicians for duty with the armed services. Under the provisions of this program 12,300 students were graduated from medical schools, such education being wholly or in part at government expense. These graduates represent only those physically qualified for commissioning in the Army of the United States, in that 20 per cent of the graduates of medical schools were found to be physically disqualified for service with the Medical Corps.

3. Of this number approximately 9,300 have served on duty with the Army, of which approximately 4,300 have been separated from active military service under the current separation criteria. During this same period the Navy under the provisions of their V-12 Program graduated 5,053 physicians from medical schools for active service with the Navy.

4. The 9-9-9 Deferment Program was established in an effort to provide sufficient resident physicians for civilian hospitals during this period, and to provide for the armed services a continual flow of physicians with additional specialty training. Under the provisions of this deferment policy all of the 9,300 A. S. T. P. graduates received nine months' internship training. Of this number one third, or approximately 3,100, were deferred an additional nine months in order to serve a junior residency; of the later group one half, or approximately 1,550, were deferred an additional nine months for the purpose of serving a senior residency (a total of twenty-seven months, the maximum allowable deferment). *Stated otherwise, 50 per cent of the A. S. T. P. graduates* who have served on active duty were deferred for additional training following the completion of internships.

5. To date, the Army has separated approximately 48,000 Medical Corps officers from active military service since VE day, including approximately 4,300 former A. S. T. P. graduates. Of this number 1,907 Medical Corps officers, ineligible under current separation criteria, were separated on the basis of their essentiality to communities requiring medical service, and 942 were separated from active military service on the basis of individual undue hardship. In addition, the Surgeon General has declared 2,907 Medical Corps officers surplus to the needs of the Army for subsequent separation. These separations have been restricted to officers returning from extended overseas service and to those who are available for reassignment. Only after a careful review of the officer's qualifications and the needs of the Army, and it has been determined that reassignment is not warranted, was an individual officer separated. This is consistent with the Surgeon General's policy of expeditiously returning the maximum number of physicians possible to civilian life.

6. On 28 February 1947 there were currently on duty approximately 7,500 physicians made up of the following categories:

Regular Army	1,125
A. S. T. P. graduates	5,050
Volunteers	
Cat. I (duration and 6 months)	650
Cat. II (until 30 June 47)	500
Other	175
Total	7,500

7. Approximately 3,200 interns, who will be called to active duty on or about 1 July 1947 unless deferred, constitute the remaining reservoir of physicians available for military service. The Surgeon General in a study determined that if 3,200 interns were called to active duty on that date the Army would possess, for several subsequent months only, a temporary excess of Medical Corps officers. It was likewise determined that subsequent to 1 January 1948 there would continue to be a shortage of approximately 1,000 Medical Corps officers for military service with the Army. The Surgeon General, therefore, recognizing the need of civilian hospitals for both junior residents and/or interns, the desirability of continuing the deferment of as many officers as possible, so that they might continue their training for subsequent military utilization, and the future shortage of Medical Corps officers for service with the Army, established the following deferment policy with the approval of the American Medical Association and related medical agencies. This deferment policy is briefly as follows:

1,200 to be deferred an additional six months from 1 July 1947, to 1 January 1948.

300 to be deferred an additional twelve months from 1 July 1947 to 1 July 1948. Priority is being given to university and teaching hospitals only.

The deadline for the submission of all requests for deferments was established to be 1 March 1947. No requests for additional deferments will be considered after this date. On 28 February 1947, 350 deferments for the additional six months, or until 1 January 1948, and 300 for the *additional twelve months, or until 1 July 1948* have been approved.

8. Officers deferred under this policy will be required to serve on active duty under the provisions of the current separation criteria coordinated and established with the Navy for Medical Corps officers, which is as follows:

a. General duty medical officers and noncritical specialists, twenty-four months' service.

b. Critical Medical Corps specialists, thirty-six months' service.

c. Terminal leave must be completed on completion of months of service as *enumerated*.

9. The Surgeon General, desiring to clarify any misunderstanding regarding current policies affecting commissioned Medical Corps officers, stresses the following points

a That veteran physicians be given priority for residency training in civilian hospitals

b Under the provisions of the current deferment policy, only 300 officers will be deferred for additional junior residency training and will thus occupy only 300 of the approximately 10,000 existing junior and senior residencies available in civilian hospitals

c That Medical Corps officers so deferred under the provisions of the deferment policy will be required to serve on active duty for the period established by the current separation criteria It is not anticipated that this will be reduced at any time in the future, in that it is neither economically or professionally feasible to utilize the services of recent graduates for a shorter period of service

d That while the combat phases of the war are at an end, the emergency is far from over On 14 February 1947 there were 43,839 patients in army hospitals, of which 6,124 were battle casualties In addition, major peace treaties are yet to be worked out, and if our country is to provide an army the size that our international commitments make necessary, medical officers must be made available to service that army

Colonel Armstrong's remarks were discussed by Miss Switzer, Dr. Abell, Lieutenant Colonel Piper, Dr. Fishbein, Dr. Shoulders, Dr Bierring, Dr. Lull and the Chairman

Dr Graham brought up the point of young physicians who had been assigned from the Army to the Veterans Administration and who found themselves, after having prepared for surgical careers, assigned to neuropsychiatric services. He thought it would be wise on the part of the Veterans Administration to make more judicious assignments of its physician personnel to the end that both the physicians and the patients would be benefited He said that he had written the Veterans Administration about the situation. Dr. Bierring thought that where "deans' committees" were in the picture in connection with veterans' hospitals such situations were not likely to occur. Dr. Lull stated that he had talked with officials of the Veterans Administration He said that the men are transferred in a block to the Veterans Administration, which assigns them; that in any given hundred men assigned there will be plenty with training in surgery or medicine but not nearly enough to handle all the vacancies in the neuropsychiatric hospitals, and that for that reason those who have had the least training in a specialty are assigned to the neuropsychiatric services

AMERICAN RED CROSS BLOOD BANK PROGRAM

Dr. Draper presented the following statement concerning the blood bank program of the American Red Cross:

The blood plasma that was surplus from the Army and Navy during the war has been distributed among the states through the state health departments, hospitals, doctors and the like and is now being used for civilian purposes The plasma, of course, is without cost to any of the agencies or individuals using it, although the cost of administration is met The supply available at the present time will be completely exhausted in about two years The rate of replenishment is not in proportion to its use, and there will be a definite shortage when the present surplus is used Owing to the experience with blood during the war, it is in increasing demand as more physicians learn how to use whole blood and to understand its methods of administration Furthermore, blood derivatives are now being discovered, and as their value is determined there will be greater demands for them Some of the best research minds of the country are working in clinical research developing new uses for blood and possible purposes for which new derivatives may be useful With that situation, the question has arisen as to what the responsibilities of the Red Cross may be According to all the figures it has been possible to gather, an adequate supply of blood for the whole nation cannot possibly be furnished through commercial sources The Executive Committee of the Red Cross Advisory Committee discussed the matter in detail and endorsed a program by the Red Cross whereby blood will be made available to people who otherwise would not be able to obtain it

There are a few state blood programs, some city programs and some private hospital blood banks The action of the Advisory Committee will be made known to the Central Committee of the Red Cross in due time In the meantime, the matter is being discussed with agencies and individuals concerned who may have helpful advice to offer

Members of the Committee asked various questions, to which Dr. Draper replied as follows·

So far there seems to be no difference of opinion as to the value of the program, the medical people feel it should be based on community needs and should receive the approval of the local medical societies for its operation in a community The Red Cross has no intention of changing a good program with adequate means for providing blood that is already in existence Consideration has been given to the possibility that without the war as a stimulus it might be difficult to obtain a large number of blood donors In the state and city programs now in operation the Red Cross is procuring donors, and there has been no difficulty in getting them, state health department officials in Massachusetts said they have been able to recruit more donors than are necessary at the present time The program being voluntary, with the Red Cross insisting that the people give their blood free of charge, no charge can be made for the product No one can tell exactly how many donors it will be possible to recruit all over the country, but people are willing to give their blood if they are convinced that it will be used to save life in the same spirit as given The Veterans Administration has priority in the distribution of blood plasma now in storage and receives what it requests The Army and Navy are paying their whole blood donors and getting their supply in that manner No consideration has yet been given to the provision of grants in aid to local agencies in the processing of the plasma program Commercial concerns are entirely willing that the Red Cross program shall proceed; they will receive payment from the Red Cross for processing the blood It will be furnished to the recipient free except for the cost of administration

Dr. Henderson stated that the Red Cross plan had been presented to the Board of Trustees of the American Medical Association and that the Board of Trustees had endorsed it in principle on the basis of community need and administration with the agreement of the local county medical society

REPORT OF SUBCOMMITTEE ON SPECIALTY BOARD FOR GENERAL PRACTITIONERS

Dr. Bierring, chairman of the Subcommittee on Specialty Board for General Practitioners, presented the following progress report·

The Subcommittee has become more and more impressed with the magnitude of this problem It is not in sympathy with the terminology "Specialty Board for General Practitioners" When specialty boards were first begun there was a background of special training in a special field There is no such background with respect to general practice and, while there is a general concept of what it means, it never has been established by an organization of physicians and surgeons in that particular field The first step has been taken in that a Section on General Practice of Medicine has been created as a part of the Scientific Assembly of the American Medical Association Certification on a national basis would not appear to be practical or advisable at this time It will require considerably more deliberation and experimentation

The recently established Indiana Board of General Practice of Medicine was described rather fully in this subcommittee's report at the last meeting However, the stated purposes for which the Indiana Board was organized were not included They are "to encourage the study, improve the practice, elevate the standards and advance the cause of the general practice of medicine by (1) creating incentive and inducement, through the prestige and distinction that accompanies recognition of achievement, to physicians to attain proficiency in the general practice of medicine, (2) developing a sense of unity and cooperation among those engaged in the general practice of medicine, (3) improving the educational opportunities of general practitioners, and (4) determining, by examination and otherwise, the competency of general practitioners who desire special recognition "

The inference is that examination should come after the other factors have been established The essential thing—and the essential thing in this Indiana plan—is first to establish a "founders' group" and to promote graduate courses in general medicine Therefore it would seem that the product is not available for certification A pattern may be found in the examination of the National Board of Medical Examiners, which is that the intern year completes a very comprehensive examination

It appears to the subcommittee that the first problem is to establish some standard to signify or specify what general practice is It should be established that there is a distinct field of medical practice referred to as general practice, and this can best be accomplished by extension courses If a program of extension courses on a national scale is considered, it should be established by the American Medical Association in cooperation with the American College of Physicians, the American College of Surgeons, the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, the American Society of Clinical Pathologists and possibly some others Then it might be possible to determine a plan for extension courses taking in the various stages general practice, diagnosis, the application of therapeutics, pharmacology, recognition of complications, minor surgery, and so on After that, certain activities could be carried on to encourage the establishment of services of general practice in the hospitals so that members of the staffs could be designated as those concerned mostly with the general practice of medicine Then there must be extended in intern service more opportunity for general practice

This attempt to "separate the sheep from the goats" is a question for much concern There is a question as to whether any very radical program developed at this time to include national certification by examination may not tend to cause a cleavage in the profession that would be most unfortunate

Dr. Sensenich, also a member of the subcommittee, presented the following statement:

> The pressure at present leaves no time for the development of a long drawn out program. The fact is that the general practitioner is being excluded from the hospitals. That is an unjustified position. There are about 21,000 diplomates of the specialty boards and about 131,000 other practicing physicians; all of the people must be taken care of and they cannot be taken care of exclusively by specialists. There is the necessity of giving the best kind of care to patients who obviously do not fall in the special groups. Some kind of action is bound to be taken somewhere. This subject has been introduced in the House of Delegates of the American Medical Association on two occasions already. It undoubtedly will be introduced again. The desire of the general practitioners to gain recognition as specialists is due in part to the Veterans Administration giving special advantage and emolument to specialists. I am confident that the thinking on this matter must be pursued further, perhaps to the standpoint that there must be less emphasis on the diplomate of the board and more on the reasons for setting up a board. It must be admitted that there is not a place for all who now aspire to specialties. The emphasis will have to be taken off the examination and the boards so that a physician is permitted to practice within reasonable bounds. It should be possible to place more emphasis on the whole program of improving the quality of medical care and to provide courses in the various states, acceptable to some national standard, for which credit—not necessarily certification—could be given, thus stimulating the general practitioner to keep his work up to date. That is a responsibility of the profession as a whole. It is being done in Colorado and in Michigan. The whole situation should be covered with a program that is practical, in which every physician will be stimulated to continue his study, will be provided with the means to that end and will receive recognition. If there is a group that wishes to provide its members with an examining board giving certification, that is incidental. It would seem to be perfectly possible and, in fact, probably should be done. To take another 10,000 off the general practitioner group and certify them, leaving the rest, is not going to solve the problem. It must be insisted that hospitals provide facilities for the care of patients by those physicians as well as by the specialty groups. It is perfectly reasonable to believe that a plan can be worked out that will provide for every one.

The subject was discussed by Miss Switzer, Dr. Sensenich and Dr. Abell. Dr. Bierring stated that the subcommittee would appreciate suggestions or advice as to how best to pursue the matter in the future. He agreed that something should be done but reminded the Committee that this is a far different problem than that of certifying limited specialists. As stated before, he said, there is no background of a special organization for general practice, although it keeps the key position in the practice of medicine. He asked if there should be thought of a council on a national basis which would establish some background of certification for general practice and of leaving the matter of certification for a later time.

It was Dr. Fishbein's opinion that the problem of how to set a standard for a general practitioner is insoluble. He thought that the key to the whole thing is hospital organization and control.

Dr. Fitzgibbon thought the first step should be to show the general practitioner that the present leaders of medicine have his welfare at heart, and that through some competent body recognition be made that a certain percentage of a hospital staff should be general practitioners.

The Chairman asked if the Joint Committee might not suggest to hospitals that they review their requirements for staff positions and, if they now limit them to certified men, whether they would not consider changing their regulations so that general practitioners will not be excluded. Dr. Bierring suggested that hospitals be informed of the situation that exists and that they be asked to reclassify or reconsider their attending staffs with a view to separating or designating a definite service in general practice. Dr. Fishbein pointed out that the members of the Joint Committee were supposed to report back to the organizations they represent and that thus there is a question as to what body should inform the hospitals. Dr. Hullerman stated that the Council on Professional Practice of the American Hospital Association has given much consideration to this subject and has not found a solution. He said that where there are boards and specialties there is a related idea that better service is obtained, and the hospitals cannot avoid recognizing that in distributing staff appointments, and that if there is an answer to the problem perhaps it could be worked out with a little more thought between the people administering the hospitals and this Joint Committee.

The Chairman asked the subcommittee to continue its study and report at the next meeting. He suggested that a report on the same subject from the American Hospital Association, the American College of Surgeons and the Catholic Hospital Association would be of interest in connection with the subcommittee's next report. After further discussion by Colonel Armstrong, Miss Switzer and Dr. Abell, the progress report of the subcommittee was accepted with appreciation.

CERTIFICATION OF GRADUATES OF FOREIGN MEDICAL SCHOOLS

The Chairman presented for the information of the Committee the following regulations promulgated by the American Board of Internal Medicine with respect to requirements for certification of graduates of foreign medical schools:

> Graduates of medical schools outside of the United States and Canada who request evaluation of their qualifications for admission to the examinations of the American Board of Internal Medicine cannot be given official consideration at this time. There is no prescribed mechanism by which the Council on Medical Education and Hospitals of the American Medical Association or any other educational agency can evaluate the quality of foreign medical education. It will therefore require, at some future date, a careful inquiry into the qualifications of each (individual) candidate who applies for consideration. It is not contemplated that individual foreign schools will be recognized.
>
> It may be possible, however, that consideration of the applications of individual physicians will be given provided the following conditions are satisfied:
>
> 1. The physician must be a citizen of the United States.
>
> 2. The physician must furnish adequate official proof that he (she) has graduated from a medical school after completing a four year full time course in medicine.
>
> 3. The physician must have a license to practice in one or more states of the United States and have been in active practice confined to internal medicine within the state of legal residence.
>
> 4. The physician must be an active member of the county and state medical societies in which he (she) has established his legal residence.
>
> 5. Graduates of foreign schools in 1930 and thereafter must, in addition to all other requirements, satisfy the requirements of one year of approved internship, three years of approved residency or fellowship in the United States, and at least two years of practice limited to the field of internal medicine.
>
> 6. Satisfaction of all the aforementioned requirements by graduates of foreign schools does not insure admission to examination any more than it does candidates graduating from approved medical schools in the United States. In all instances the Board exercises its privilege of careful investigation of all candidates. Standards of achievement and satisfactory performance will be required of all.

REPORT OF SUBCOMMITTEE TO STUDY TAFT-FULBRIGHT BILL

The members of the Subcommittee to Study the Taft-Fulbright Bill, Dr. Bierring, Chairman, Miss Switzer and Dr. Sensenich, reported as follows:

DR. BIERRING: It has been announced that the first hearings on S. 140, the Taft-Fulbright bill, will be held on Feb. 28, 1947. A companion bill, H. R. 573, has been introduced in the House by Representative Harris of Arkansas. The purpose of the Taft-Fulbright bill is to create an executive department of the Government to be known as the Department of Health, Education and Security, with a Secretary who will have Cabinet rank and three under secretaries for Health, Education and Security. The bill provides that the Under Secretary for Health shall be a doctor of medicine licensed to practice medicine or surgery in one of the states or territories of the United States or in the District of Columbia. It also provides that Freedman's Hospital, the U. S. Public Health Service, the Food and Drug Administration and the Federal Board of Hospitalization shall be transferred to the Division of Health. The new department would be authorized to promote the general welfare by aiding and fostering programs in the field of health, education and security and related services contributing to individual, family and community well-being. The use of state and local agencies, including both public and voluntary, is more fully designated in this bill than in any previous one of the kind.

MISS SWITZER: There is some difference of opinion on the provisions of S. 140 as now drafted. The Federal Security Agency feels it is a mistake to have three rigid divisions set by statute and would prefer more flexibility. For example, the Children's Bureau is at present intact and a part of the Social Security Administration. Should it remain there, thus giving much more emphasis to its welfare programs, or should it go into the new Division of Health? As far as money goes, as you know, the major part of its program is in the health field. Then there is the Office of Vocational Rehabilitation: Should that go to the Division of Education or of Health? It is felt that it would be hampering and a great disadvantage to freeze a new department of such importance as this would be with three rigid statutory divisions. Also it is rather questionable as to whether or not the professional qualifications of political officers should be written into a statute as is done in this bill. Such requirements do not exist in any other department, and it would be much better in the long run to have this new department follow traditional lines. It is felt that if a Cabinet post is created it ought to be with the general agreement of all groups concerned. Unless that can be accomplished, there may be stirred up competition and bitterness which would impede a good program. It is thought, too, that the mandatory provisions in this bill about dealing with state and local public and voluntary organizations are very questionable; it would be preferable to have a strong statement of the intent of Congress that the Department work with professional and voluntary groups; the way it is now written it would be mandatory that quacks and borderline organizations have the same relationship with the Department as agencies of a different type. One other provision which it is felt is not wise gives the Secretary power to abolish bureaus and to transfer to himself the function of the established bureaus. That is extremely dangerous.

In the field of health and education, there is a feeling that this movement for a new department has been sponsored by people in the welfare field, who will have dominance. The movement for separation in the health and education groups is strong. One organization that is doing more than any of the others to try to coordinate is the National Social Welfare Assembly, which has combined with the American Council on Education and has set up a committee that is trying to develop a consensus among its members. Dr. Lull and Dr. James R. Miller of Hartford, Conn., are representing the American Medical Association on this committee. Other members in the medical field are Dr. Vlado A. Getting, Dr. Ernest L. Stebbins, Dr. Ira V. Hiscock and Dr. Robin C. Buerki. The committee is preparing a rather good statement, which tries to set forth the pros and cons of the controversial reports.

Dr. Sensenich: The American Medical Association was approached to send representatives to the conference called by the National Social Welfare Assembly and the American Council on Education on January 31, at which the committee mentioned by Miss Switzer was set up. Dr. Miller and Dr. Lull represented the Association at the conference. After the meeting of this Joint Committee on January 11, when I was appointed a member of the Subcommittee to study the Taft-Fulbright bill, it was decided that I should attend the conference. Most of the time was taken up with feeling out the various groups as to what their attitudes would really be. They were very cautious. No one spoke out openly for the proposal, and the only one who spoke definitely was Mr. Nelson H. Cruikshank, Director of Social Insurance Activities of the A. F. of L., and he was against it. He stated that the American Federation of Labor would have nothing to do with it; he thought that all of social security and health which have to do with industry should be in the Department of Labor. Education apparently was not too much interested either, and the hospital group I think were not too much for it either. However, these are just impressions.

Federal security asserts that the head of medical affairs need not necessarily be a physician and that the head of the Education Division need not be an outstanding educator. It is a political structure. From that point on, the bill is definitely a welfare bill to which there will be objection.

RURAL MEDICAL SERVICE

Dr. Mulholland presented the following statement on the activities of the Committee on Rural Medical Service:

Since the January meeting of the Joint Committee, the second National Conference on Rural Health has been held. The attendance at the conference was above expectations, registration being over three hundred. The discussions pertinent to the subject and the cooperation between representatives of rural organizations and physicians were excellent. Definite recommendations were sent to the Board of Trustees of the American Medical Association and will be briefly sketched. It should be noted that in many instances different panels naturally arrived at the same conclusions.

It was suggested that there be clarification of the term "health center," but in the discussions it was brought out that no one definition would fit because of the various types of health centers. It was repeatedly suggested that the population in rural areas be educated with reference to the problems incident to rural medical practice and the important part that communities must play in getting and maintaining medical facilities in these rural communities. This can be brought about only by concerted community action. It was suggested, and indeed it seems highly important, that the American Medical Association stimulate the formation of state and county health centers, composed of physicians, dentists, farm groups and others interested in the health problem, to study the needs and develop definite plans.

In order to retain physicians and dentists in rural areas, it was felt that there should be provision of adequate medical facilities and a reasonable income for physicians and dentists, stimulation of practice in groups and a concomitant improvement of community educational and cultural facilities and extension of good roads. It was recognized that the problem was tied in with the economic status of these areas. It was urged that medical schools place more emphasis on the economic problems of medicine in the medical school curriculum, and that students be given practical experience in rural medicine. A successful rural medical organization should include rotation of interns through a coordinated hospital system.

Voluntary medical prepayment plans were discussed at some length, and it was urged that, in addition to extension, enrolment policies be considerably broadened and serious attention given to the possibility of these plans covering services for the medically needy.

With reference to nursing, emphasis was placed on education in the home, expansion of home nursing courses in high schools, development of practical nursing services and improvement of the status and compensation commensurate with the education required.

Panel discussions on medical care for lower income groups suggested that state and local funds implemented by federal grants be urged. It was stated that this lower income group would include about 85 per cent of the total population, which points up the importance of this problem. A suggestion was made that the various effective tax supported medical care plans now in operation be given careful study and that cooperative health associations be expanded and developed on a community level.

The Chairman thanked Dr. Mulholland for his presentation and stated that the report shows important progress and that it is gratifying to note the interest of the farm organizations.

EVALUATION AND DEVEOPMENT OF RESEARCH PERSONNEL

Miss Switzer informed the Committee that she was working with two committees in Washington which have to do with scientific personnel, including medical; two very exhaustive studies are under way on how to insure the development of a sufficient number of competent students in research fields; the President's Board in cooperation with the National Research Council is trying to survey existing personnel and project the need for the future; another committtee is trying to take a long range veiw of what ought to be done in continued stimulation of scientific personnel and has a responsibility to the War and Navy departments based on the experience in this war as to adjustments necessary.

Dr. Dearing stated that the U. S. Public Health Service is busily engaged in recruiting both physicians and scientists and is emphasizing in the universities the opportunities for scientists in the Public Health Service and the Fellowship program, which it is expected will be expanded next year.

SHORTAGE OF NURSING PERSONNEL

Dr. Hullerman brought the matter of a shortage of nursing personnel to the attention of the Joint Committee, as follows:

During the past year and a half the Committee on Careers in Nursing, under the auspices of the National Nursing Council, has been responsible for what recruitment there has been of student nurses. The work of the committee was done without the expenditure of much money and largely by means of national radio programs, prepared advertisements sent free on request to newspapers, some paid magazine advertising, some distribution of literature and answering of inquiries. It was evident last summer that when this committee would go out of existence because of the dissolution of the National Nursing Council there would be no program this year.

A plan has been drawn up, with no representation of professional people, providing for the establishment of a committee to be empowered to collect funds and conduct the recruitment program. The Board of Trustees of the American Hospital Association took no action on the Careers in Nursing Committee. The National League of Nursing Education did appropriate a small sum. The Council on Professional Practice and the Board of Trustees of the American Hospital Association are of the opinion that the matter of student nurse recruiting is of utmost importance to the public. The American Hospital Association consulted last week with the National Nursing Council and has appropriated a sum of money to carry on immediately a nurse recruitment program and expects to go to the schools and hospitals for further funds. There should be on the recruitment committee representatives from the Joint Committee for the Coordination of Medical Activities—or from the American Medical Association—as well as from the various nursing organizations.

In addition, there is a possibility of the establishment of an assistance program to hospitals in the form of short, two day institutes.

For the first time in months a definite program is in the offing, and it has been thought that the Joint Committee might wish to support it and to give financial aid as well, because it is going to require a considerable outlay of money.

Dr. Sensenich asked if the proposed fund would be largely consumed in the national spread or if it would be used to help local areas, and Dr. Hullerman replied that local areas would have to carry on their own programs.

It was the opinion of the Chairman that the Joint Committee could help to promote the project in its liaison capacity with the organizations its members represent.

TIME AND PLACE OF NEXT MEETING

It was voted to hold the next meeting at American Medical Association Headquarters in Chicago on Saturday morning, April 26, 1947.

The meeting adjourned at 1:20 p. m.

Washington Letter

(From a Special Correspondent)

May 22, 1947.

Restoration of Million Dollars Asked for Psychiatric Training and Research

Eugene Meyer, owner of the Washington *Post* and former president of the National Committee on Mental Hygiene, asked the Senate Appropriations Committee to restore a House cut of $1,100,000 in funds for psychiatric training and research. Witnesses described national facilities in the field as totally inadequate. Mr. Meyer said that elimination of this item from the training and research activities of the U. S. Public Health Service would be harmful. He said there was less training and research in mental health problems than in other medical fields.

Elimination of Tuberculosis Within Generation Predicted

Tuberculosis, chief cause of death among Americans during their most productive years, 15 to 40, could be eliminated within a generation with medical weapons recently acquired, health experts report. Dr. Herman E. Hilleboe, assistant surgeon general, U. S. Public Health Service, believes that a national program against the disease should set up a nationwide case finding program along the lines of those used in cities like Chicago, care for disease victims, find jobs for "cured" patients or patients with the disease in an arrested form or place them where they will not be subjected again to the disease. Dr. Hilleboe says that the new high speed x-ray equipment using small film is one of the greatest developments in controlling the disease. Chests of the entire adult population could be x-rayed in a short time with this equipment.

President Truman Speaks on Observance of National Hospital Day

In a letter to the American Hospital Association on the twenty-seventh annual observance of National Hospital Day, President Truman declared that it was "an appropriate time to focus public attention on the inadequacies of our present hospital facilities . . . and to rally public support for the hospital program recently authorized by Congress under the Hospital Survey and Constitution Act." Mr. Truman explained that the measure authorizes expenditures of $1,250,000,000 for hospital building with federal aid in the next five years, adding that "we are looking forward to the day when hospital service will be expanded and to a program of hospital management whereby more citizens can be treated at a cost within their means."

Penicillin Reported to Be Cure for Seventy per Cent of Syphilitic Cases

A U. S. Public Health Service conference attended by 150 leading doctors and research experts was informed that penicillin is now a cure for 70 per cent of cases of infectious syphilis, and the drug will prevent syphilis in all but 5 per cent of babies born to syphilitic mothers. Effectiveness of penicillin in treating syphilis in thirty-six "rapid cure" clinics throughout the nation was reported by Dr. Margaret Merrell of Johns Hopkins University.

Dr. Parran Calls for Unified Attack on Pollution of Waterways

Surg. Gen. Thomas Parran of the U. S. Public Health Service informed the Senate Public Works Committee that there should be a unified attack against pollution of the nation's waterways to produce a "healthier America." He spoke on behalf of a bill calling for a federal outlay of $100,000,000 annually over a ten year period to give federal assistance to communities in combating pollution.

Surplus Anesthetic Agents Offered for Sale by War Assets Administration

The War Assets Administration has announced that $220,000 worth of government surplus anesthetic agents have been offered for sale in a fixed price sale to hospitals, hospital and surgical supply houses, pharmaceutical, drug and chemical manufacturers and exporters. Brochures are available from WAA regional offices.

Coming Medical Meetings

American Medical Association, Atlantic City, June 9-13. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Association for the Surgery of Trauma, Atlantic City, Hotel Claridge, June 5-7. Dr. Gordon M. Morrison, 520 Commonwealth Ave., Boston 15, Secretary.

Aero Medical Association of the United States, Atlantic City, Ritz-Carlton Hotel, June 4-6. Dr. David S. Brachman, 1016 Dime Bldg., Detroit 26, Secretary.

American Association for Thoracic Surgery, St. Louis, May 28-30. Dr. Richard H. Meade Jr., 55 E. Washington St., Chicago 2, Secretary.

American Association of Genito-Urinary Surgeons, Absecon, N. J., June 4-6. Dr. Charles C. Higgins, 2020 E. 93d St., Cleveland 6, Secretary

American Association of the History of Medicine, Cleveland, May 25-26. Dr. Howard Dittrick, 2020 E. 93d St., Cleveland 6, Secretary.

American Association on Mental Deficiency, St. Paul, Minn., May 28-31. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American College of Allergists, Atlantic City, Hotel Senator, June 6-8. Dr. Fred W. Wittich, 401 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Chest Physicians, Atlantic City, Ambassador Hotel, June 5-8. Mr. Murray Kornfeld, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Radiology, Atlantic City, Haddon Hall, June 7-8. Mr. Mac F. Cahal, 20 N. Wacker Drive, Chicago 6, Executive Secretary.

American Dermatological Association, Murray Bay, Quebec, Can., June 1-5. Dr. Harry R. Foerster, 208 E. Wisconsin Ave., Milwaukee, Wis., Secretary.

American Diabetes Association, Atlantic City, Chalfonte-Haddon Hall, June 7-8. Dr. Cecil Striker, 1019 Provident Bank Bldg., Cincinnati 2, Secretary.

American Geriatrics Society, Atlantic City, Hotel Brighton, June 5-7. Dr. Malford W. Thewlis, 25 Mechanic St., Wakefield, R. I., Secretary.

American Heart Association, Atlantic City, Hotel President, June 6-7. Dr. Howard B. Sprague, 50 W. 50th St., New York, Secretary.

American Medical Women's Association, Atlantic City, Hotel Claridge, June 7-8. Dr. Helen F. Schrack, 216 N. Fifth St., Camden, N. J., Secretary.

American Neisserian Medical Society, Atlantic City, Marlborough-Blenheim Hotel, June 8. Dr. William L. Fleming, 750 Harrison Ave., Boston, Secretary.

American Neurological Association, Atlantic City, Marlborough-Blenheim Hotel, June 16-18. Dr. Walter O. Klingman, 195 Ft. Washington Ave., New York 32, Secretary.

American Ophthalmological Society, Hot Springs, Va., June 5-7. Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

American Proctologic Society, Atlantic City, June 7-8. Dr. Harry E. Bacon, 2031 Locust St., Philadelphia 3, Secretary.

American Radium Society, Atlantic City, June 8. Dr. Hugh F. Hare, 605 Commonwealth Ave., Boston 15, Secretary.

American Rheumatism Association, Atlantic City, Ritz-Carlton Hotel, June 7. Dr. Richard H. Freyberg, 321 E. 42d St., New York 17, Secretary.

American Society for the Study of Sterility, Atlantic City, Hotel Strand, June 7-8. Dr. John O. Haman, 490 Post St., San Francisco 2, Secretary.

American Society of Clinical Pathologists, Atlantic City, June 4-8. Dr. Alfred S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

American Society of Electroencephalography, Atlantic City, Marlborough-Blenheim Hotel, June 13-14. Dr. Robert S. Schwab, Massachusetts General Hospital, Boston 14, Secretary.

American Therapeutic Society, Atlantic City, Chalfonte Hotel, June 6-7. Dr. Oscar B. Hunter, 1835 I St., N. W., Washington 6, D. C., Secretary.

American Urological Association, Buffalo, N. Y., Hotel Statler, June 30-July 3. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Association for the Study of Internal Secretions, Atlantic City, June 6-7. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Idaho State Medical Association, Sun Valley, June 16-19. Dr. William B. Handford, Caldwell, Secretary.

Maine Medical Association, York Harbor, Marshall House, June 22-24. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Medical Library Association, Cleveland, Wade Park Manor, May 27-29. Miss Heath Babcock, New York State Medical Library, Albany 1, New York, Secretary.

Minnesota State Medical Association, Duluth, June 30-July 2. Dr. B. B. Souster, Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Montana, Medical Association of, Missoula, June 26-28. Dr. H. T. Caraway, 115 N. 28th St., Billings, Secretary.

National Gastroenterological Association, Atlantic City, Hotel Chelsea, June 4-6. Dr. G. Randolph Manning, Room 319, 1819 Broadway, New York, Secretary.

National Tuberculosis Association, San Francisco, June 16-19. Dr. F. D. Hopkins, 1790 Broadway, New York 19, Executive Secretary.

New Hampshire Medical Society, Portsmouth, Hotel Wentworth, June 19-20. Dr. Carleton R. Metcalf, 5 South State Street, Concord, Secretary.

New York State Association of Public Health Laboratories, Syracuse, May 27. Miss Mary B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

North Dakota State Medical Association, Fargo, May 25-27. Dr. L. W. Larson, 221 Fifth St., Bismarck, Secretary.

Society of Surgeons of New Jersey, Atlantic City, Seaview Country Club, May 28. Dr. Walter B. Mount, 21 Plymouth St., Montclair, N. J., Secretary.

South Dakota State Medical Association, Rapid City, May 31-June 3. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

Wyoming State Medical Society, Sheridan, June 23-25. Dr. George E. Baker, 226 E. 2d St., Casper, Secretary.

Medical Legislation

STATE LEGISLATION

California

Bills Passed.—S. 353, which passed the house May 6, proposes the enactment of a **hospital survey and construction act** for the purpose of causing a statewide survey of hospital facilities and the formulating of a plan for the construction of additional needed facilities as well as the establishment of an advisory hospital council. The survey would be administered by the state department of public health, which would be appointed as the state agency to accept money received from the federal government for state assistance in either survey or construction programs. S. 1071, which passed the house May 5, proposes that the use or prescribing for or administering to himself of cocaine, opium, morphine, codeine, heroin, alpha eucaine, beta eucaine, chloral hydrate, paraldehyde or barbituric acid, **any of the narcotics or alcoholic beverages** to an extent which is injurious to his practice, by any person licensed under the provisions of the business and professions code shall constitute unprofessional conduct.

Bills Enacted.—S. Con. Res. 31, which has become resolution chapter 98 of the Laws of 1947, authorizes the director of the state department of public health to investigate the problem of **rheumatic fever** and rheumatic heart disease as it affects the children in the state who are in need of diagnostic treatment and hospital and convalescent care, including occupational therapy, medical social services and school health programs related to this disease and the costs of such care, the facilities needed to provide for them. S. 348, which has become chapter 199 of the Laws of 1947, amends the health and safety code relating to poisons by including **osteopaths** within the definition of the term "physician." S. 972, which has become chapter 151 of the Laws of 1947, authorizes the state **board of chiropractic examiners** to approve chiropractic schools and colleges whose graduates may apply for licenses in the state and to set forth certain requirements which schools must meet in order to be eligible for such approval.

Connecticut

Bill Passed.—H. 953, which passed the house May 7, proposes to authorize licensed physicians to prescribe means or methods for the **temporary prevention of pregnancy** in a married woman when, in the opinion of such physician, pregnancy would endanger the life or injure the health of such woman.

Florida

Bills Introduced.—S. 358, to amend the existing law requiring physicians, osteopaths and dentists to designate properly their school of practice in a **sign at the entrance of their office**, proposes that any one engaged in the practice of any of the other healing arts, including naturopathy and chiropractic, must do the same thing. The proposal would exclude those engaged in the practice of the religious tenets of any church. S. 437 proposes the creation and establishment of a University of **Florida School of Medicine** and Dentistry to be located in Hillsborough County.

Bills Passed.—S. 151, which passed the senate May 6, to amend the law relating to the practice of massage, proposes to redefine the meaning of the practice so as to include the use of electrical apparatus. S. 245, which passed the house May 7, proposes to authorize the superintendent of the Florida State Hospital, when unable to obtain **necessary medical personnel** from within the state, to employ competent, experienced medical personnel from outside the state of Florida and proposes further that personnel so employed shall be exempt from existing requirements of law as to time of residence in the state and also as to requirements relating to the passing of an examination in the basic sciences.

Illinois

Bill Introduced.—H 514 proposes the issuance of **chiropractic licenses** by the department of registration and education Chiropractic is defined to be "the science of palpating and adjusting the articulations of the human spinal column, correcting interference with nerve transmission and expression, to restore health, without the use of drugs or surgery."

Iowa

Bill Enacted.—H. J. R. 10, which was approved April 29, 1947, designates a **mental health authority** in the state, to consist of at least one practicing psychiatrist, for the purpose of directing the benefits of Public Law 487 of the Seventy-Ninth Congress of the United States.

Maine

Bills Passed.—S. 449, which passed the house April 29, proposes to authorize the governor to appoint an advisory hospital council to advise and consult with the department of health and welfare in carrying out the administration of the existing **hospital survey act.** S. 529, which was approved May 10, 1947, requires an **annual examination for tuberculosis** of all superintendents of schools, supervisors, teachers, school nurses, janitors, school bus drivers and persons employed in the preparation of school lunches.

Maryland

Bill Enacted.—H. 69, which has become chapter 906 of the Laws of 1947, provides for the creation of a state board of **physical therapy examiners** and defines physical therapy as "the treatment of human injuries, diseases or disabilities by means of the healing properties of exercise, massage, ultraviolet rays, mechanical devices, heat, cold, air, light, water and electricity, but not by means of roentgen rays, radium, surgery or drugs." Among other things, the law also states that a physical therapist is one who treats only patients diagnosed and referred by licensed medical doctors.

Massachusetts

Bill Introduced.—S 308 proposes the enactment of a nonoccupational accident and **sickness benefits law.**

Bill Enacted.—H. 1919, which has become chapter 369 of the Laws of 1947, provides that any person who was a resident of the commonwealth for a period of five years prior to July 1, 1941 who matriculated at any medical school in the commonwealth prior to said date and who since that time received a degree of doctor of medicine from such school shall be eligible to apply for registration as a qualified physician, shall be **examined by the board of registration** in medicine and shall be subject to all the provisions of the law relating to such eligibility and examination.

Michigan

Bills Introduced.—H. 204 proposes the enactment of a licensing law for **privately owned hospitals**, homes and institutions for the care and treatment of mentally diseased persons. H. 378, to amend the law relating to marriage, proposes that any person seeking **a marriage license** shall present either a certificate showing graduation from the eighth grade or the certificate of a practicing physician or psychologist that the applicant is not feebleminded. H. 500 proposes the creation of a state **department of mental health** for the humane, curative, scientific and economical treatment of persons mentally ill. S. 378 proposes to require that all children prior to registration for the first time in any of the public or private schools, kindergartens, day nurseries or any other preelementary schools in the state shall give evidence that they have been **properly immunized** against diphtheria, whooping cough and smallpox. Exempted from the act are children whose parents or legal guardian have religious objections to such immunization.

Bill Passed.—S. 215, which passed the senate April 29, proposes to amend the law relating to mentally diseased persons so as to authorize **osteopaths** to execute the required certificates of insanity, feeblemindedness or epilepsy.

Missouri

Bills Introduced.—S. 117, which was approved May 6, 1947 to amend the law relating to the practice of medicine and surgery, requires the **biennial registration** of all physicians in the state. S. 121, which was approved May 6, 1947, requires the annual registration of all persons licensed to practice **osteopathy.** At the time of such annual registration the applicant must present evidence that he has attended at least one of the two day educational programs conducted by the Missouri Association of Osteopathic Physicians and Surgeons, or its equivalent, during the prior year.

New Hampshire

Bill Passed.—H. 448, which passed the house May 6, proposes to require every physician attending **a pregnant woman** for conditions relating to the pregnancy to take or cause to be taken a sample of blood of such woman at the time of the first examination and to submit such sample to an approved laboratory for a standard serologic test for syphilis

Ohio

Bill Passed.—H. 294, which passed the senate May 8, proposes to amend the law relating to the **practice of chiropody** by authorizing the state board of medical examiners to adopt rules and regulations permitting in the practice of chiropody the use of such drugs as are necessary to such practice.

Oklahoma

Bill Enacted.—H. 226, which was approved May 5, 1947, prohibits **advertising of prices** by any professional group within the state.

Pennsylvania

Bill Introduced.—H. 1321 proposes an **appropriation** to the Lancaster Heart Association for the purpose of research, study, prevention and care of rheumatic fever and diseases of the heart.

Bills Enacted.—H. 905, which has become Act No. 73 of the Acts of 1947, amends the law relating to the **practice of osteopathy** by extending until June 30, 1948 the requirement of a nine months internship prior to examination. H. 917, which has become Act No. 72 of the Acts of 1947, amends the medical practice act by repealing the 1943 law which reduced for a limited period of time the training period of medical **internship in hospitals.** H. 921, which has become Act No. 74 of the Acts of 1947, amends the medical practice act by repealing the 1943 law authorizing the issuance of **temporary permits to practice** medicine under certain conditions.

South Carolina

Bills Passed.—H. 300, which passed the house May 6, proposes the establishment of **ten annual medical scholarships** of the annual value of $550 each to be given to bona fide residents of the state of South Carolina who agree, after the completion of their medical training, to begin promptly and thereafter engage continuously in the general practice of medicine in a rural community in the state for a period of years equal in number to the years that he has been a beneficiary of such scholarship. S. 721, which passed the house May 9, proposes a law requiring the licensing, inspecting and **regulating of hospitals** and related institutions within the state.

Wisconsin

Bill Passed.—S. 162, which passed the house May 1, proposes to require all physicians to report immediately to the local health officer the name, age and address of every person diagnosed as afflicted with **epilepsy** or similar disorders characterized by lapses of consciousness.

Bill Enacted.—S. 159, which has become chapter 68 of the Laws of 1947, authorizes counties to **purchase and equip ambulances** for conveyance of the sick or injured and to make reasonable charges for the use thereof.

GOVERNMENT SERVICES

ARMY

CASE OF SMALLPOX ON ARMY TRANSPORT

A Puerto Rican mess steward suffering from smallpox was removed from an army transport at Bremerhaven, Germany, March 27, following the voyage from New York The 23 year old whose residence is in Manhattan was aboard the ship in New York from March 4 to 14, when the transport sailed for Germany, during which period he visited relatives The transport was held in quarantine for fourteen days in Germany and then embarked for the return to the United States carrying 1,760 passengers, of whom 1,230 were vaccinated against smallpox during the return voyage

SYMPOSIUM AT ARMY MEDICAL CENTER

The Surgeon General, Major Gen Norman T. Kirk, has sent out invitations to a symposium to be held at the Walter Reed General Hospital, Army Medical Center, Washington, D. C, June 3-5. Among the subjects to be discussed will be.

"U. S. Army Experiences with Streptomycin," by Major Edward J. Pulaski, chief, Surgical Research Unit, Brooke General Hospital, Fort Sam Houston, Texas.

"Medical Aspects of the Atomic Bomb," by Col James P. Cooney, medical director, Military Application Division, Atomic Energy Commission, Washington, D. C.

"The Newer Concepts of Amputations and Prostheses," by Col. August W. Spittler, Orthopedic Section, Walter Reed General Hospital, Washington, D. C.

"Results of 100 Cases of Plastic Surgery," by Dr. Donald W Macomber, consultant in plastic surgery, Fitzsimons General Hospital, Denver.

"Recent Advances in the Treatment of Lung Abscess," by Dr. Brian B Blades, consultant in thoracic surgery, Walter Reed General Hospital, Washington, D. C.

"What Physical Medicine Has to Offer the Medical and Surgical Practitioner," by Dr Frank H. Krusen, head of the Section on Physical Medicine, Mayo Clinic, Rochester, Minn

"Latest Developments in Malaria Therapy," by Dr Alf S Alving, professor of medicine, University of Chicago

"Streptomycin in the Treatment of Tuberculosis," by Lieut. Col. John B Wallace, M. C., and Lieut George W Fishburn, Fitzsimons General Hospital, Denver.

"The Physiologic Effects of Wounds as Guides for Treatment of Freshly Wounded Men," by Dr Henry K Beecher, chief anesthetist, Massachusetts General Hospital, Boston

"Clinical Pathologic Conference,' by Col Virgil Cornell, M C, chief, laboratory service, Walter Reed General Hospital

"Intensive Psychotherapy," by Dr. Norman Q. Brill, Veterans Administration, Washington, D. C, and consultant in neuropsychiatry, Walter Reed General Hospital

"Research in Virus Diseases," by Dr. Joseph E. Smadel, scientific director, Department of Virus and Rickettsial Diseases, Army Medical Department Research and Graduate School, Washington, D C

"Testicular Tumors," by Dr. Lloyd G. Lewis, consultant in urology, Walter Reed General Hospital.

"Newer Concepts of Control of Respiratory Diseases," by Dr Colin MacLeod, professor of bacteriology, postgraduate division, New York University College of Medicine, New York.

"The Federal Contribution to the Health and Welfare of the Nation," by U. S Senator James E Murray of Montana

At the banquet Wednesday Evening in the Washington Hotel the toastmaster will be the Surgeon General and the speaker the Secretary of War, Hon Robert P Patterson

IMPROVEMENT IN HEALTH IN JAPAN

Col Crawford F. Sams, chief, Public Health and Welfare Section, General Headquarters, Supreme Commander for the Allied Powers, Tokyo, recently stated that Japan has made as much progress in public health in the eighteen months since the Japanese surrender as have other modern nations in eighteen years. According to the New York *Times* the death rates have dropped from 30.5 to 18. Among other things accomplished under the supervision of the Supreme Commander for the Allied Powers are virtually universal smallpox vaccination, 34,000,000 diphtheria immunizations, 13,000,000 typhoid vaccinations and 5,000,000 inoculations against tuberculosis. Typhus, smallpox, diphtheria, typhoid and paratyphoid have shown impressive reductions, both in case rates and in death rates. Only dysentery has shown an increase. The supposed "alarming" increase in the number of cases of tuberculosis and syphilis reported arose not from increases in these diseases but from the fact that for the first time these diseases were really being reported

GENERAL MacARTHUR'S REPORT ON JAPAN

The War Department, in summarizing General MacArthur's report of activities in Japan for January, stated that diphtheria declined by 50 per cent in 1946 and that dysentery, typhoid paratyphoid and scarlet fever rates also declined. Only smallpox and typhus increased in 1946.

In a previous report from General MacArthur's headquarters the cholera epidemic in South Korea was said to have ended in November. The total number of cases during the epidemic was reported as 15,615, with 10,191 deaths

At that time a shortage of typhus vaccine necessitated holding all available stocks as a reserve for immunizing contacts, repatriates and essential personnel. By the end of November, the report states, 925,474 Koreans had been brought back to Korea from Japan and 92,088 from other Pacific areas. By the same date 878,145 Japanese nationals had been repatriated from North and South Korea.

A program of weekly lectures for all Korean physicians was begun in November at Seoul National University and was aimed at stimulating interest in improved medical standards, with emphasis on diagnosis, therapeutic procedures and the use of American drugs; a pamphlet on the use of American drugs was also distributed to doctors and drug merchants.

MEDICAL RESERVE GENERALS

Among the general officers in the U. S. Army Reserve recently appointed by the War Department were Brig. Gen. Stanhope Bayne-Jones of Yale University School of Medicine and Dr. Isidore S. Ravdin, professor of surgery at the University of Pennsylvania Medical School, Philadelphia. During the recent war General Bayne-Jones was director of the United States of America Typhus Commission and was assistant chief of the Preventive Medicine Service in the Surgeon General's Office, while General Ravdin was commanding officer of the 20th General Hospital in the China-Burma-India Theater.

BUTTER FOR THE ARMY

The requirements for butter for the present decreased strength of the armed forces will be such a small percentage of the nation's productive capacity that it is not expected to have any effect on the civilian supply. The butter requirements for the Army the entire year 1947 will be about 38,500,000 pounds Two years ago when the armed forces were at their peak the Army procured 314,500,000 pounds, or more than 23 per cent of the nation's butter. The army butter requirements are calculated on the basis of 1.11 ounces daily per man

LIBRARY NEWS

Atherton Seidell, Ph D., an honorary consultant of the Army Medical Library, has gone to Paris, France, to install free microfilm copying service in certain libraries in France, including that of the Academie de médecine and Ecole de pharmacie.

The executive committee of the honorary consultants to the Army Medical Library will meet May 27 at the Allen Memorial Library in Cleveland

NAVY

EXAMINATIONS FOR APPOINTMENT IN THE NAVY

Examination for the selection of candidates as doctors in the Navy will be held at all naval hospitals in the United States, June 23-27. Successful candidates will be appointed to the grade of assistant surgeon in the Medical Corps and will have the rank of lieutenant, junior grade. Only graduates of approved medical schools in the United States or Canada who have completed their intern training in accredited hospitals, or those who will have completed such training within four months of the date of examination and who are physically and in other respects qualified, are eligible for the examination Candidates, who must be less than 32 years of age at the time of appointment, will be required to appear before boards of medical examiners and supervisory naval examining boards at the naval hospital nearest their residence for the full period of the examination in connection with demonstrating their physical and professional qualifications for appointment. Following approval by the President of the United States and confirmation by the Senate, selected candidates will be issued an appointment and orders assigning them to duty in a naval medical facility for active naval service.

Information as to form and procedure of application may be obtained from the offices of Naval Officer Procurement or from the Bureau of Medicine and Surgery, Naval Department, Washington 25, D. C.

MARINE INTERHOSPITAL CLINICAL MEETING

The Marine Hospital Medical and Dental Association will hold a three day clinical meeting at the Marine Hospital in Baltimore, May 23-24. Clinicians from other Marine hospitals and some civilians' hospitals will take part in surgical, medical, tumor and dental clinics and demonstrations. There will be exhibits, motion pictures, forums, a business session and a dinner meeting Friday evening at which Dr. Henry N. Harkins, associate professor of surgery at Johns Hopkins University, will speak on vagotomy for peptic ulcer. Members of the profession are invited to attend.

NAVY AWARDS AND COMMENDATIONS

Captain Earl Richison

The Bronze Star Medal has been awarded to Capt. Earl Richison (MC), U.S.N. The citation read as follows: "For meritorious service in connection with operation against the enemy while serving as the division surgeon of a Marine division of Wellington, New Zealand, from Feb. 6 to July 1, 1943. Captain Richison was charged with the responsibility of acquiring hospitalization of diagnosed cases of malaria contracted during the operation on Guadalcanal by about two thirds of the personnel of the division. His acquisition of additional places for hospitalization from the New Zealand government, expert professional knowledge of the treatment of malaria and the skilful and efficient coordination of the medical organizations of the division resulted in the successful restoration to duty of the vast majority of the malarial patients. His remarkable achievements contributed to the ultimate success achieved by the division in subsequent operations against the enemy. Throughout the entire period his professional ability, untiring efforts and devotion to duty were outstanding and thoroughly in keeping with the highest traditions of the United States Naval Service." Dr. Richison graduated from the University of Louisville School of Medicine in 1915 and entered the military service Sept. 6, 1917.

VETERANS ADMINISTRATION

MEDICAL CARE OF VETERANS

PAUL B. MAGNUSON, M.D.
Washington, D. C.

The medical profession knows how to handle big jobs. But it has never faced a greater challenge than that offered by the Veterans Administration in its program of "medical care second to none" for veterans of the nation's wars

Most of us have failed to appreciate the magnitude of this one agency's task. With its plans for peacetime only barely begun, the Veterans Administration was unprepared for the tremendous workload which was suddenly thrust on it in the rapid demobilization which followed VJ day. Skilled hands were called on to do a job and do it quickly. Under a leader who used bold, imaginative strokes to catch up with and master its fast growing problems, the agency has been able to meet the immediate demands of veterans with surprising success. And, like any organization which is determined to produce results rather than explanations, it has been the subject of misinformation, unfounded rumors and more than its share of unwarranted criticism.

As a member of the medical profession who happens to be in a position to know at first hand the objectives and problems of this vast organization, I believe I can contribute something to a better understanding of its work. I came to Washington intending to stay six months; the six have already stretched out to sixteen busy, interesting and highly rewarding months. This is the nation's greatest single humanitarian undertaking, a project which cannot help but produce a tremendous impact on the social and economic welfare of its citizens.

The Veterans Administration has grown during the past twenty months from a complacent, routine minded organization serving the 4 million veterans of World War I and previous wars to a progressive and aggressive agency geared to handle the needs of 20 million veterans. There has been a startling expansion in all departments to meet the staggering load. A total of sixty-four separate programs are now under way to provide the benefits enacted by the Congress to ease the peacetime readjustment of America's fighting men.

In little more than a year and a half, the Veterans Administration has handled 5,500,000 pension and compensation claims by veterans and their dependents. Payments in disability benefits have amounted to more than $1,865,000,000.

During the same period it guaranteed $3,875,000,000 worth of veterans' loans on homes, businesses and farms.

The agency paid out more than $2,000,000,000 in readjustment allowances.

In those same months it handled almost 6,500,000 applications for education and training and paid out more than $2,000,000,000 in subsistence and tuition.

At the same time its work aided in some measure the rapid return of more than 11,000,000 veterans to peacetime jobs.

These figures are more than mere statistics. They tell a story of human reconversion from war to peace.

But it is in the medical care, in meeting the immediate and vital needs of sick and wounded veterans, that the greatest and most satisfying progress has been made. Where treatment of veterans in hospitals and outpatient departments was once held to a more or less passive and laggard standard, it is now on a par with that to be found in our best civilian hospitals and is being increased and improved as rapidly as the resources and means for its advancement can be found. It is the largest medical service in the world, already handling a patient load 800 per cent greater than that of a few years ago.

To a practitioner, this spells good medicine and a chance to do something worth while. In my own case I would not have stayed in Washington longer than the six months I planned on if I did not believe, as I do now, that this is an unprecedented opportunity for the medical profession to demonstrate that it can do so tremendous a job in treating patients, advancing medical research and education and, most important, working with a government agency on a cooperative basis to provide good medicine.

I want to stress the fact that the practice of medicine in the Veterans Administration is not dictated from Washington. Those who have engaged in or watched our program can testify that the treatment of patients and allied education and research activities are conducted and supervised locally. Wherever there are medical schools they have cooperated in this plan. The progress that has been made by the medical profession in developing and carrying out the plan during the past fifteen months has amazed every one who knows about it; our trouble, unfortunately, is that the full facts are not generally known.

In any organization, large or small, there are always people who are cold or only lukewarm to the success and outcome of a new idea. Departure is shot at much more frequently than the routine practice to which people have become accustomed. We have had our shooting—from behind bushes and from straight out in front. There have been mistakes. Any organization which increases in size and responsibility as the Veterans Administration has done is bound to make mistakes. But we are fully aware of them and determined to do something about them. We have some bugs, but we also have DDT. We are going to use enough of the DDT on the bugs to eliminate most of them.

There are some who misjudge the caliber and zeal of the men who make and direct Veterans Administration policies. They fear that the present program is too revolutionary in concept and practice to last for long in the face of repeated obstacles. But they are wrong. Despite the fact that ours is a battle in the practice of medicine that is being fought and prepared for at the same time, we are confident that we shall be successful if given the continued support of the American people. General Bradley has stated repeatedly and emphatically that the quality of medical service to veterans will not be sacrificed for any reason. He has refused to be discouraged by temporary setbacks and has consistently supported General Hawley in plans to improve rather than reduce our medical services.

It is up to the medical profession to continue the splendid efforts which have earned the faith and confidence of veterans and the general public alike in the medical treatment provided by the Veterans Administration. A few chiselers can often blind most people to the good work being done by their sincere and conscientious associates. But the final pay off is what counts, and chiselers seldom last until then.

I write this from the heart because I want my fellow practitioners to know that we here in Washington appreciate their efforts and the job they have done. We look forward to their continued cooperation and assistance. With that, I am sure General Bradley and General Hawley will make good the promises which we as a nation have made to our veterans. Isn't that what all of us really want?

Veterans Administration, Washington 25, D. C.

MENTAL HYGIENE CLINIC AT DURHAM, N. C.

The new building for the Veterans Administration mental hygiene clinic at *Duke University School of Medicine, Durham,* N. C., which was expected to be ready about April 1, will house fifteen consultation and treatment offices and other facilities necessary for the treatment of mentally ill veterans. The professional staff of the clinic will comprise eleven Veterans Administration psychiatrists, nurses, a shop instructor and five members of the faculty of Duke University School of Medicine, who will work closely with the clinic. This, the only clinic of its kind in North Carolina, will service the whole state. The chief psychiatrist is Dr. George Sutherland; the liaison officer between the clinic and Duke Hospital will be Dr. Leslie B. Hohman, while the work of the hospital and the clinic will be coordinated by Dr. Richard S. Lyman, professor of neuropsychiatry, and Dr. Maurice Greenhill of the neuropsychiatry department.

MORE BOOKS FOR VETERANS' LIBRARIES

More than 15,000 books were added to the shelves of Veterans Administration hospital libraries during January, bringing the total number of volumes to 828,313, including fiction and nonfiction of a general nature for veteran patients and technical works for VA medical personnel. The more than 90,000 patients in VA hospitals and homes read a total of 213,230 books during the month. Hospital libraries for patients are maintained in 119 of the 126 hospitals and homes of the Veterans Administration.

PERSONAL

Dr. Cameron S. Guild, executive secretary of the American Trudeau Society, New York, has been appointed assistant chief, tuberculosis section, Veterans Administration Branch Office No. 12, San Francisco, which office has supervision over veterans' activities in California, Arizona, Nevada and Hawaii. Dr. Guild, a native of Canada, came to the United States in 1925, was associated with the Mississippi State Board of Health at Tupelo for several years and was consultant to the U. S. Public Health Service and director of special programs for the National Tuberculosis Association. During the first world war he was a flight lieutenant in the Royal Flying Corps.

PHYSIATRISTS NEEDED

An urgent need for physiatrists prevails at the Veterans *Administration Hospital,* Hines, Ill. This hospital has about 3,000 patients. The physical medicine service includes patients from the medical, surgical, neuropsychiatric and tuberculosis services. If interested, write to Dr. K. A. Carroll, manager, stating training, background and experience in physical medicine.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration is conducting sales of surplus government property announced by the following regional offices. *Physicians* who are veterans have certain priorities in the purchase of this government property.

Regional Office, 704 Race Street, Cincinnati. Sale of drugs, blood transfusion apparatus, x-ray field unit (portable), dressing sterilizers, surgeon's needles, surgical scissors, bandages. Sale closes May 26.

Regional Office, 95th and Troost, Kansas City, Mo. Sale of curets, forceps, surgeon's gloves, hot water bags, ice bags, hospital beds. Sale closes June 4.

Regional Office, 37 Broadway, New York. Sale of hospital and x-ray equipment and supplies, gauze bandages, x-ray film development holder, tray trucks, dressing forceps, surgical needles. Sale closes May 27.

Regional Office, 699 Ponce de Leon Avenue Northeast, Atlanta, Ga. Sale of drugs, dental, surgical and hospital equipment and accessories. Sale opens May 9 and will be continuous.

Regional Office, 7700 Wallisville Road, Houston 1, Texas. Sale of laboratory, x-ray and hospital equipment. Sale closes May 26.

Regional Office, 404 South Wabash Avenue, Chicago. Sale of lens grinding, centering and polishing machines. Sale closes June 10.

Regional Office, 1409 Second Avenue, Seattle. Sale of folding operating tables, instrument tables, electric instrument sterilizers, operating lamps, specialists' chairs, oxygen therapy outfit and sphygmomanometers. Sale closes May 26.

Regional Office, 505 North Seventh Street, St. Louis. Sale of surgical and dental instruments and hospital and laboratory equipment. Sale closes June 5.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ALABAMA

State Medical Election.—At its recent meeting the Medical Association of the State of Alabama elected Dr. Jesse P. Chapman, Selma, president; Dr. Edward L. Gibson, Enterprise, vice president, and Dr. Daniel G. Gill, Montgomery, state health officer. Mobile was chosen as the site for next year's convention.

Public Health Building.—A contract for the construction of a $649,983 public health building at the University of Alabama Medical Center, Birmingham, has been approved by the governor. Funds will be provided by the state, Jefferson County and the city of Birmingham. The Alabama Building Commission allocated $225,000, Jefferson County $100,000 and Birmingham $175,000.

ARKANSAS

Society News.—At the semiannual meeting of the first councilor District Medical Society, May 1 in Tyronza, Dr. T. Duel Brown, Little Rock, spoke on "Diagnosis and Treatment of Diseases of the Prostate"; Dr. Mervin H. Grossman, Tyronza, "The Autopsy from the General Practitioner's Viewpoint"; Dr. F. Walter Carruthers, Little Rock, "Common Fractures and Problems of Interest," and Dr. William H. Anderson, Booneville, Miss., "The Future of the Small Town Physician and the Small Town Hospital." Following the dinner Dr. Robert L. Sanders, Memphis, Tenn., spoke on "Vagotomy—the Indications, Technic and Results."

CALIFORNIA

Examination Date Postponed.—The examination for director of clinical services, Mental Institution, which was announced for June 14, has been postponed to June 19, and the closing date on applications has been postponed to May 29.

Three Outbreaks of Food Poisoning in San Francisco.—Three separate outbreaks of food poisoning occurred in a prominent men's club in San Francisco within two days, affecting about 100 persons. An investigation disclosed that hollandaise sauce was the common factor and that hemolytic Staphylococcus aureus was present. The sauce cook had been employed for a number of years. After a conference with leading chefs the San Francisco Department of Public Health adopted regulations for the preparation, storage and service of hollandaise sauce which, it is hoped, will minimize the possibilities of future similar outbreaks.

Field Study of Encephalitis.—A group of scientists of the Hooper Foundation of the University of California Medical Center, University of California School of Medicine, San Francisco, will set up a field laboratory in Bakersfield in cooperation with the State Department of Public Health and Kern County Health Department and Kern County Hospital, Bakersfield, to study encephalitis during its season from May to September. Annually the disease strikes about 1,000 victims in the hot valleys of California, notably the San Joaquin and Sacramento. Heading the program is Dr. William McD. Hammon, epidemiologist of the university's Hooper Foundation. The study has the backing of the National Foundation for Infantile Paralysis, the Bureau of Game Conservation, the U. S. Public Health Service and the U. S. Army.

Los Angeles County Association Wins Radio Award.—The radio program "If They Had Lived Today," sponsored by the Los Angeles County Medical Association, has been judged the best public interest program series created in the United States during 1946. The award, made by the College of the City of New York, was the only top award, made in the form of a plaque, for any type of radio program in the West. Professor John G. Peatman, Ph.D., College of the City of New York and chairman of the committee of awards, said that the plaques are the highest awards given for classes of competition and are presented for outstanding achievement in program creation and promotion. "If They Had Lived Today" was originated by Mr. Stanley K. Cochems, executive secretary of the Los Angeles County Medical Association, in July 1946. It presents a series of dramatic incidents from the lives of great men of history. At the conclusion of the dramatic rendition the cause of death or disability of the dramatized person is discussed, with emphasis placed on the fact that if he had lived today he could have been helped by modern medical science. The program has been heard over station KGFJ at 5:45 p. m. three times a week since its inception.

COLORADO

Personal.—Dr. DeWitt S. Lowe, Colorado Springs, has left for Korea, where he will resume work as medical missionary of the Presbyterian Church. Dr. Lowe left Korea in 1941 after having been imprisoned five months by the Japanese.

Postgraduate Course in Chest Diseases.—A clinical postgraduate course in chest diseases will be given by the American Trudeau Society at the University of Colorado School of Medicine, Denver, from July 28 through August 9. Registration will be limited to thirty. Preference will be given applicants from the Rocky Mountain section. For further information write Dr. Cameron St. C. Guild, executive secretary, American Trudeau Society, 1790 Broadway, New York 19.

DISTRICT OF COLUMBIA

Dedication of Physicians' Window at Washington Cathedral.—The physicians' window, the first of a series of three cathedral windows recognizing the leading professions and their relation to religion, will be dedicated at the Washington Cathedral June 1, 4 p. m. The speaker will be Dr. Frank J. Sladen, physician in chief at the Henry Ford Hospital, Detroit, and his subject will be Religion and Medicine. Dr. Sladen, a graduate and former member of the faculty of Johns Hopkins University School of Medicine, Baltimore, went to Detroit in 1913. He is a trustee of the Henry Ford Hospital and of the McCormick Theological Seminary in Chicago. The physicians' window at the Washington Cathedral was given by the widow of the late Dr. Elmer B. Freeman, a widely known gastroenterologist. The other two windows, to be installed later, will symbolize the professions of education and law.

ILLINOIS

Typhoid Outbreak.—During the first three weeks of April about 25 cases of typhoid were reported from the area around Palmer and Morrisonville in Christian County. The source of the outbreak was traced to ice cream contaminated by a food handler who, unknown to himself, was a typhoid carrier.

Chicago

Dr. Parran to Speak on Health Survey.—Dr. Thomas Parran, Washington, D. C., Surgeon General, U. S. Public Health Service, will speak on the Chicago-Cook County Health Survey at a luncheon meeting of the Council of Social Agencies of Chicago May 26 at the Standard Club at 12 noon. Reservations can be made at the office of the council, 343 South Dearborn Street.

Meeting of Anesthetists.—The American Society of Anesthesiologists will hold a regional meeting in conjunction with the Chicago society May 29-30. Clinical demonstrations are scheduled Thursday at Research and Educational Hospitals, University of Illinois, Wesley Memorial, St. Luke's, Michael Reese and Evanston hospitals and the University of Chicago Clinics. Conferences will begin at 1:30 p. m. May 30, and dinner round tables with moderators and an evening symposium on nitrous oxide will complete the two day program.

A Tribute to Army Nurses.—Michael Reese Hospital has published the story of the 16th EVAC, an army medical unit in which fifty of its personnel served in the recent war. The unit, called to active duty Oct. 15, 1942, trained five months in Florida and after a bouncing twenty-eight day cruise landed in Oran, Algeria, and later served in the Sicilian invasion, going ashore in assault craft the first day at Salerno. The nurses arrived nine days after the hospital was set up and the hospital began to spruce up immediately: Patients were bathed, medicine bottles shined, flowers in empty plasma cans appeared in the wards, and morale soared.

> "The femininity of army nurses is an obstinate and hard-cored habit which even the rigors of life in the field cannot alter. Their little wall tents were embellished with frills and dainty bric-a-brac. A crate became an attractive table with a bright colored piece of cloth. Though steel helmets served as laundry tubs, wash day was an indispensable routine, and the nostalgic spectacle of lingerie drying in the breeze was a common sight. Under their O. D. bandannas, nurses wore their hair in curlers. Nationally advertised beauty products were found in every tent, and self-performed permanents and facials were the rule until a sizable town was reached, when the nurses made a beeline for the first beauty parlor available."

En route to Salerno the hospital ship on which the nurses had embarked was bombed, requiring them to transfer to a warship and return to Bizerte for a short time then back to Sicily to join the unit. This, the first in a series of pamphlets about Michael Reese Hospital, is illustrated by very apt drawings of various situations made by a member of the unit. The hospital later was transferred to the Italian mainland, serving in the battle of Cassino and the Anzio landing, where during one day and night 473 patients were admitted and more than 200 operated on. The unit moved up the peninsula to Ardenza and took part in the battle of the crossing of the Arno River, the battle for the Gothic line and the advance to the North into the Po Valley. News of the surrender of Japan reached the unit on Aug. 12, 1945, and within a month the unit was on its way back home, some by cattle boat, others by mule ships and others on luxury liners.

INDIANA

County General Practitioner Society.—Dr. Harry R. Kerr, Indianapolis, was chosen chairman of the new Marion County Society of General Practitioners, recently organized Dr. Henry F. Nolting was named vice chairman and Dr. Lester D. Bibler secretary-treasurer, both of Indianapolis. Three general practitioners from each hospital were named to serve on the executive committee.

University Appointments. — Dr. Dwain N. Walcher, instructor in pediatrics at Yale University, New Haven, 1943-1946, has been appointed to the newly created post of assistant professor of pediatrics in the Indiana University School of Medicine, Bloomington. Dr. Walcher is a graduate of the University of Chicago School of Medicine, Chicago. Dr. Louis W. Spolyar, since 1930 director of the Division of Industrial Hygiene for the Indiana State Board of Health, has been named to the newly created post of the assistant professor of public health (part time). A graduate *cum laude* of Indiana University School of Medicine, Bloomington-Indianapolis, he has done postgraduate work in industrial medicine at the University of Michigan Medical School, Ann Arbor.

IOWA

Program to Aid Blind Children.—The State Commission for the Blind will offer a week in training on the campus of the Iowa School for the Blind, Vinton, for mothers with visually handicapped children under 5 years of age. The program will provide a preschool training program in which mothers will become acquainted with the type of training beneficial to the children. Matrons will look after the children so that mothers may attend meetings and visit together. There is no registration fee, and board and room will be provided for both mothers and children. For information address Mr. Leslie M. Hays, Superintendent, Iowa School for the Blind, Vinton.

KENTUCKY

Advisory Health Council.—An advisory council to aid the state board of health in promoting a health center and hospital program has been named by the governor. Physician members of the council, approved on request of the United States Public Health Service, are Drs. Hugh Houston, Murray; Luther Bach, Newport; W. Clark Bailey, Harlan; Clyde Sparks, Ashland, and Virgil G. Kinnaird, Lancaster.

MAINE

Change in Health Officer. — Dr. Roscoe L. Mitchell, Augusta, retired as director of the State Bureau of Health May 1. Dr. Mitchell, who will return to private practice, had been with the State Department of Health and Welfare since 1930.

Poliomyelitis Preparedness.—The State Bureau of Health and the state of Maine county chapters of the National Foundation for Infantile Paralysis on May 15 held a poliomyelitis preparedness meeting at the State House, Augusta. The meeting consisted of a general session in the morning and two panel sessions in the afternoon, one for professional personnel and one for chapter personnel.

MARYLAND

Cancer Control Program.—A division of cancer control has been created in the bureau of medical services of the state department of health. The director of the state board of health and the medical director of the Maryland division of the American Cancer Society have expressed the desire that the two organizations join forces in a state program. Dr. W. Ross Cameron, Baltimore, assistant director of welfare for medical care, and Dr. Howard W. Jones Jr., Baltimore, Maryland division of the American Cancer Society, will assume joint responsibility for the development of a program including statistical studies, educational activities and the organization of adequate preventive diagnostic and treatment facilities.

Mass Chest X-Rays.—The Maryland State Department of Health early in April began a statewide chest x-ray survey following its acceptance of a $27,000 tractor and trailer unit from the Westinghouse Electric Corporation. The fully equipped mobile laboratory contains facilities for developing chest pictures much faster and at less cost than the usual systems. The health department expects to make x-rays of the population at the rate of 6,000 to 7,000 a month.

MASSACHUSETTS

Alumni Meetings in Atlantic City.—The annual meeting and dinner of the Harvard Medical Alumni Association will be held at the Hotel Claridge, Atlantic City, June 11 at 7 p m ——The Tufts Medical Alumni Association will hold a dinner June 11 at 6:30 p. m. at the Ritz-Carlton Hotel in Atlantic City.

New School of Nursing at Boston University.—Formal dedication and opening of Boston University School of Nursing at 160 Beacon Street took place April 30. It is now organized with a basic professional division and an advanced professional division. The resources of all fourteen colleges and schools of the university are utilized to provide the academic program The hospitals with which arrangements are being made to carry out the expanded nursing programs are the Peter Bent Brigham, Children's, Boston Lying-In and Boston Psychopathic. The Massachusetts General Hospital continues to be associated with the program in the preparation of orthopedic nurses and teacher training. The advanced professional division offers nursing specialization curriculums in advanced clinical nursing, public health nursing and nursing education. The school offers the degrees of Bachelor of Science or Master of Science in nursing education and a Master of Science in nursing

MICHIGAN

Another Rapid Treatment Center.—A new venereal disease rapid treatment center for residents of Detroit and Wayne County opened March 24 in the Herman Kiefer Hospital, Detroit. Funds are provided by Wayne County and the U. S Public Health Service through the state health department.

Committee on Awards.—The Council of the Michigan State Medical Society recently named three persons and one organization for recognition as having performed meritorious service in the cause of health: (1) Charles F. Kettering, director of research, General Motors, Detroit; (2) Emmet Richards, chairman of the Michigan Crippled Children Commission and president of the Michigan Society for Crippled Children and Disabled Adults; (3) Percy Angove, director, Michigan Society for Crippled Children and Disabled Adults, and (4) the Michigan Society for Crippled Children and Adults. The action grew out of recommendations of the newly created Committee on Awards, which was named to formulate early this year procedures and recommend policies which would permit the Michigan State Medical Society properly to honor those lay organizations and lay personages who, in the opinion of the society, had contributed service of distinct worth in the causes of health to the people of Michigan. Awards are of three grades: (1) a letter of recommendation, (2) a printed certificate of accomplishment and (3) a hand illuminated scroll.

MINNESOTA

The Mayo Memorial. — The Committee of Founders appointed in 1943 to select a memorial to Drs. William J. and Charles H. Mayo are asking for $350,000 still needed to complete the $3,000,000 construction cost for the Memorial Medical Center at the University of Minnesota, Minneapolis. The legislature has granted $1,500,000. More than 3,000 corporations and individuals have subscribed $1,162,000, leaving about $350,000 still to be subscribed. The plans provide for a central nineteen story tower unit which will be connected with the Medical Sciences Building by a four story extension which will use the Mayo Memorial Auditorium with a seating capacity of 600. An underground garage will be provided for about 200 cars.

MISSOURI

Epidemic Among Infants in St. Louis.—Since the first of the year 33 babies have died of gastroenteritis at two hospitals in St. Louis. The outbreak now is believed to be checked in both institutions. The maternity ward of one of the municipal hospitals where 22 deaths occurred has been closed and a new one opened. Similar steps have been taken at De Paul Hospital.

Course in Encephalographic Technology.—The Washington University School of Medicine, St. Louis, will establish a department of electroencephalographic technology next fall under the direction of Dr. James O'Leary, associate professor of neurology. The eight month course beginning October 1 will be divided into three trimesters. Prerequisite for the course is graduation from an approved high school in the upper two thirds of the graduating class.

NEW HAMPSHIRE

New England Health Institute.—Health and education workers of New England will attend a health institute June 16-18 at the University of New Hampshire, Durham. The subjects included in the program are public health administration, school health, health education, cancer, laboratories, industrial health and hygiene, vital statistics, maternal and child health, communicable diseases and tuberculosis control. Among the speakers will be Philip Drinker, LL.D., and Constantin P. Yaglou, School of Public Health, Harvard University, Boston; Dr. Louis Schwartz, Washington, D. C., U. S. Public Health Service; Dr. Halbert L. Dunn, Washington, D. C., and Dr. Kenneth F. Maxcy, Johns Hopkins School of Hygiene and Public Health, Baltimore. A banquet will be held Tuesday evening at 6:30 and a luncheon Wednesday noon at which Dr. Reginald M. Atwater, New York, executive secretary, American Public Health Association, will speak.

NEW YORK

Academy Awards Medal to Dr. Thomas.—The Rochester Academy of Medicine will present the Albert David Kaiser Medal for 1947 to Dr. Clarence P. Thomas at its annual meeting this month. The medal is awarded for unusually meritorious contributions to scientific research or service to the entire community. Dr. Thomas was chosen for giving the most important war service among local physicians in civilian practice. He was chairman of the Medical Defense Committee and deputy chief of the emergency medical service of Rochester. He is a graduate of the Columbia University College of Physicians and Surgeons, New York, and served in the first world war. He is vice president of the Rochester Academy of Medicine, assistant professor of medicine at the University of Rochester School of Medicine and Dentistry and a member of the Strong Memorial Hospital staff.

New York City

Academy Awards Medal to Dr. James A. Miller.—The convocation meeting that marked the end of the centennial celebration of the New York Academy of Medicine was held April 24. Dr. George Baehr, New York, president, presented the Academy Medal to Dr. James A. Miller, New York, past president. Dr. Miller, a fellow of the academy since 1904, has served on the committee of public relations since 1911. The award was presented to Dr. Miller as "a distinguished medical scientist in recognition of outstanding service to humanity."

Appoint Director of University-Bellevue Medical Center.—Mr. Edwin A. Salmon, chairman of the City Planning Commission, has been appointed director of the New York University-Bellevue Medical Center, which he has served from its beginning as consultant to the faculty planning committee. In his new position Mr. Salmon will also be responsible for the coordination of the medical center with other hospital and health agencies. Included in this project will be a 480 bed university hospital, an institute of rehabilitation and an institute of forensic medicine.

PENNSYLVANIA

Meeting of Ophthalmologists and Otolaryngologists.—The Pennsylvania Academy of Ophthalmology and Otolaryngology held its annual meeting April 26-27 at the Penn-Harris Hotel, Harrisburg. Guest speakers at the meeting were Dr. William L. Benedict, Mayo Clinic, Rochester, Minn., whose subject was "Tumors of the Orbit," and Dr. LeRoy M. Polvogt, associate professor of otolaryngology, Johns Hopkins Medical School, Baltimore, "Irradiation of the Nasopharynx."

Philadelphia

Personal.—Dr. Donald C. Smelzer, Philadelphia, managing director of Germantown Dispensary and Hospital, has been chosen to represent the American Hospital Association at the meeting of the International Hospital Federation in Lucerne, Switzerland, May 27-29. Dr. Smelzer is past president of the association and will be the guest of the Swiss Hospital Association.

GENERAL

Reunion of Pennsylvania's Class of '39.—The 1939 class of the University of Pennsylvania School of Medicine, Philadelphia, will hold a reunion and buffet supper in the solarium of the Hotel Claridge, Atlantic City, Wednesday, June 11, from 5 to 7 p. m.

Rush Alumni Luncheon in Atlantic City.—The Rush Medical College Alumni Association will have a luncheon meeting June 11 at 12 noon at the Hotel Claridge. Advanced reservations may be made with Dr. Grant H. Laing, secretary, 104 South Michigan Avenue, Chicago.

Two New Cancer Journals.—The American Cancer Society announces the publication of two new journals: *Cancer News*, inaugurated in January, is published for the public; *Cancer*, a professional journal for distribution to the medical profession, is scheduled for publication late this summer.

Appointed to American Board of Obstetrics and Gynecology.—Drs. Edward A. Schumann, Philadelphia, and Ward F. Seeley, Detroit, are to serve as associate examiners, in addition to those whose names were published in The Journal March 29, page 956, for the coming examination of the American Board of Obstetrics and Gynecology, to be held in Pittsburgh June 1-7.

Red Cross Desires Old Journals.—The National Headquarters of the American Red Cross, Washington, D. C., would like to secure copies of several back issues of the *American Journal of the Medical Sciences* in order to send them to the International Red Cross for use of the Netherlands Red Cross Societies. Persons desiring to donate certain specified back issues on this journal should write American Red Cross, the Chicago chapter, Community Service to Camps and Hospitals, 529 South Wabash Avenue, or call Wabash 7850, extension 79.

Dr. Rajchman to Head United Nations Children's Emergency Fund.—Dr. Ludwig Rajchman, Polish delegate to the United Nations, has been elected chairman of the board of the International Children's Emergency Fund. Executive director of the fund is Maurice Pate, former director of the Prisoners' War Relief Division of the American Red Cross. The International Children's Emergency Fund was created by the United Nations General Assembly "for the benefit of children and adolescents of countries which were victims of aggression and of countries receiving UNRRA relief, and for child health purposes generally, giving high priority to the children of countries victims of aggression."

Dr. McCord Wins Knudsen Award in Industrial Medicine.—At the thirty-second annual meeting of the American Association of Industrial Physicians and Surgeons, Buffalo, May 1, the William S. Knudsen Award was presented to Dr. Carey P. McCord, Detroit, for his book "A Blind Hog's Acorns." The award is given annually for the most distinguished contribution to that field of medicine. Dr. McCord's book won recognition for "driving home convincingly the role of medicine as contributing eminently to the safety and well being of men and women in industry." It is concerned with the never ending search for occupational diseases and relates the doctor's personal experiences in an assortment of medical detective stories.

Conference of State Presidents in Atlantic City.—The third annual conference of presidents and other officers of state medical associations will be held June 8 at 1:30 p. m. in the Trellis Room of the Ritz-Carlton Hotel. Dr. L. Howard Schriver, Cincinnati, president-elect and president, Associated Medical Care Plans, Inc., will speak on "The Medical Profession's Program to Improve Medical Care"; Major Gen. Paul R. Hawley, Washington, D. C., U. S. Army, retired, chief medical director, Veterans Administration, "Cooperation of the Medical Profession with the Veterans Administration," and Robert A. Taft, Washington, D. C., U. S. senator from Ohio, "Health Legislation in Congress." Committee reports, election of officers and executive committeemen and a discussion period led by Dr. Andrew S. Brunk, Detroit, past president, will follow the program.

Financial Help for Poliomyelitis Patients.—The National Foundation for Infantile Paralysis, 120 Broadway, New York, will assist financially those patients suffering from infantile paralysis who require such help. The American people have made this possible through their generous contributions to the March of Dimes. Hospital bills, salaries for physical therapists, nurses, purchase of special equipment and many other charges which may be essential to good medical care may be paid for by the chapters of the National Foundation when necessary. There is a chapter of the National Foundation in or near practically every community in the United States, and the local health department can furnish the address of the nearest chapter Physicians should notify their local chapter when a poliomyelitis patient comes under their supervision and should notify the family of the patient of the existence of the local chapter and its willingness to assist Last year 25,191 cases of poliomyelitis occurred in this nation, constituting the largest outbreak since 1916 Obviously the number of cases that will occur this year cannot be foretold

Vascular Surgeons Meeting in Atlantic City —The Society of Vascular Surgery will hold an open meeting at 2 p m June 8 at the Hotel Dennis Among the speakers will be.

Dr Alton Ochsner, head of department of surgery, Tulane University of Louisiana School of Medicine, New Orleans Venous Thrombosis

Dr Robert R Linton instructor in surgery, Harvard Medical School, Boston, Postthrombotic States of the Lower Extremity Treatment by Superficial Femoral Vein Interruption, Ligation and Stripping of Long and Short Saphenous Veins

Dr Alfred Blalock, professor of surgery Johns Hopkins University School of Medicine, Baltimore Congenital Pulmonic Stenosis

Dr Robert E Gross assistant professor of children's surgery Harvard Medical School, Boston, Surgical Treatment of Coarctation of the Aorta

Dr Emile Holman, professor of surgery Stanford University School of Medicine, Stanford University, San Francisco, Experimental Studies in Cardiac Hypertrophy

Dr Harris B Shumacker, associate professor of surgery, Yale University School of Medicine, New Haven, Conn , Causalgia

Dr Michael E DeBakey, assistant professor of surgery, Tulane University of Louisiana School of Medicine, Hemometakinesia and Its Therapeutic Significance in Peripheral Vascular Diseases

Annual Golf Tournament at Atlantic City.—The American Medical Golfing Association will hold its thirty-first tournament Monday, June 9, at the Linwood Country Club, Atlantic City, N J , for those playing 36 holes and at the Atlantic City Country Club for fellows who plan only one round Registration at both clubs Hours for teeing off 7 30 a m to 2 p m for the 36 hole competition At least twenty-five trophies and prizes for experts and beginners will be awarded Present your official handicap certified by your home club secretary No handicap over 30 Twelve dollars covers green fees at either club (not both), luncheon at either club and dinner at Atlantic City County Club, prizes, entertainment and annual golf dues New fellows pay an enrolment fee of $3 For transportation, call Yellow Cab, Atlantic City 4-1221, state you are playing in the American Medical Golf Tournament and cab will pick you up at your hotel Four dollars each way regardless of the number of passengers Please notify the chairman, Dr Jean A Gruhler, 101 South Indiana Avenue, Atlantic City, N J , at once if you are coming and if you plan to play 36 or 18 holes

Immunization for Latin American Travel.—According to the *State Department Bulletin* of Sept 12, 1946 the immunization requirements of Caribbean and Central and South American countries are those listed here The symbols C, S, T and Y are used for cholera, smallpox, typhus and yellow fever respectively

Argentina	S Y	Honduras	S, T
Bolivia	S T Y	British Honduras	C, S, T
Brazil	S T Y	*Mexico	S T
Chile	S T Y	Nicaragua	T
Colombia	S, T, Y	Panama	Y
Costa Rica	S, T	Paraguay	S, Y
Ecuador	S T, Y	Peru	S T, Y
El Salvador	S T	Uruguay	S
Guatemala	S, T	Venezuela	S, T
The Guianas	Y		

*In Mexico a smallpox certificate is required of all persons except tourists or persons in transit

No immunization is required by Antigua , Bahamas, B W I ; Barbados, B W I , Bermuda , Canal Zone , Cuba , Dominican Republic , Haiti , Jamaica , Martinique , Santa Lucia (Br.) , St Pierre Miquelon, Trinidad, B W I , Virgin Islands These requirements are minimal Immunization against smallpox and typhoid-paratyphoid infections is probably advisable for travelers in any of the Latin American areas, and other immunizations may be advisable depending on the area to be visited

Dr. Stebbins Succeeds Dr. Weed as Head of Red Cross Advisory Board—Dr Ernest L Stebbins, Baltimore, director of the school of hygiene and public health of Johns Hopkins University, Baltimore, has been appointed chairman of the advisory board on health services of the American Red Cross, succeeding Dr Lewis H Weed, Baltimore, head of the division of medical sciences, National Research Council In recognition of his past services, Dr Weed was presented with a special Red Cross citation on his retirement During 1946 Dr Stebbins surveyed medical aspects of the American Red Cross civilian relief program in Europe He toured sixteen countries and in conjunction with local medical authorities made recommendations for rebuilding their medical facilities He also served as American Red Cross representative at a meeting of the medical commission of the League of Red Cross Societies at Oxford, England Dr Stebbins, a graduate of Rush Medical College, Chicago, who holds a master's degree in public health from Johns Hopkins University, served as epidemiologist with the state health departments in Virginia and New York He also served New York State as director of the division of communicable diseases and as assistant commissioner of health and held the post of health commissioner for New York city Prior to joining the Johns Hopkins University staff, Dr Stebbins was professor of epidemiology at the Columbia University College of Physicians and Surgeons, New York

DOMINICAN REPUBLIC

Thirteen New Hospitals—Thirteen new hospitals are soon to be constructed in the Dominican Republic as part of a public health program that has already produced some of the most modern hospitals in the Caribbean area For the furtherance of the public health program the 1947 budget appropriation for the Department of Sanitation and Public Health has been increased by $420,592 over the 1946 allotment, bringing this year's total to $2,187,064 Two of the new hospitals are to be built in Ciudad Trujillo, the capital, at a cost of $250,000 each and are to be very similar in construction to the new Dr William A Morgan Hospital for workmen and their families, which was opened recently in the new low priced housing neighborhood

FOREIGN

United Nations Health Unit in Singapore.—The United Nations World Health Organization will direct its epidemiologic control in the Far East from Singapore, using the same bureau the League of Nations used before it recently turned its work over to the WHO The bureau will be used to report and distribute information on pestilent diseases in the Far East

Registry of Bone Tumors.—A registry of primary malignant tumors of bones has been set up in the department of pathology, Royal College of Surgeons, London, England, to collect records of cases, especially those in which cure or prolonged alleviation has been attained by treatment All cases claimed as five year cures will be considered by the committee, but in the future only cases in which histologic proof of the nature of the tumor can be obtained will be considered Those interested are invited to send records with amputation or biopsy specimens to Professor R A Willis at the college, Lincoln's Inn Fields, London W. C 2 Donors will be sent reports on the investigation of specimens received and will be asked for follow-up information

Deaths in Other Countries

Dr. Christian Frederic Louis Leipoldt died April 12 in Capetown, South Africa, aged 67 He had been the editor of the *Medical Journal of South Africa,* a lecturer in children's diseases at Capetown University and was once personal physician to Joseph Pulitzer, publisher of the New York *World*

Sir Almroth Wright, M D, originator of vaccination against typhoid, died April 30 at his home, Farnham Common, Buckinghamshire, England, aged 85

Marriages

Oscar Milton Wilbur Jr, Cape Cottage Woods, Maine, to Miss Anna Louise Wells of Sumter, S C, in Rochester, N Y, Nov 16, 1946

Philip Marion Winslow, Rochester, N Y, to Miss Daisy Hunter Wood of Coral Gables, Fla, Nov 27, 1946

Joseph W Anderson, Ardmore, Pa, to Mrs Olive U Green of Whitehall in Bryn Mawr Oct 9, 1946

William Martin Dickerson, Conway, Ark, to Miss Betty Jean Sheperd of Ambia, Ind, February 2

George C Armistead Jr, Roanoke, Va, to Miss Margaret Skinner of Holyoke, Mass, January 11

Harold James Black, Mendota Mo, to Mrs Jessie Clarke Kirby in Washington, D C, March 8

Foster J Boyd, Cincinnati, to Miss Francis Laird of Huntington, W Va, February 15

Harold D Carnahan, Spokane, Wash, to Mrs Caroline Fitzgerald at Deer Park in January

Harvey R Cummins to Miss Osa Massen, both of Los Angeles, February 16

Deaths

Walter Ivan Lillie ⊕ Philadelphia; born in Grand Haven, Mich., Nov. 5, 1891; University of Michigan Medical School, Ann Arbor, 1915; professor and head of the department of ophthalmology at the Temple University School of Medicine; entered the Mayo Clinic in Rochester, Minn., as first assistant in ophthalmology in 1917; held a fellowship at the Mayo Foundation; later associate in ophthalmology at the Mayo Clinic and associate professor of ophthalmology at the Mayo Foundation; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society and the Association for Research in Ophthalmology; fellow of the American College of Surgeons; consulting ophthalmologist at the Temple University Hospital, Shriners' Hospital for Crippled Children in Philadelphia, Eagleville (Pa.) Sanatorium for Consumptives and the Norristown (Pa.) State Hospital; served in the British and American Expeditionary Forces in France during World War I; died February 21, aged 55, of heart disease.

George Thomason ⊕ Los Angeles; born in Camden, N. J., Nov. 6, 1872; Jefferson Medical College of Philadelphia, 1899; L.R.C.P. and L.R.C.S., Ireland, in 1904; professor and head of the department of general surgery at the College of Medical Evangelists; a member of the founders group of the American Board of Surgery; member of the Western Surgical Association; fellow of the American College of Surgeons; since 1934 member of the state board of medical examiners; at one time assistant surgeon at the Battle Creek (Mich.) Sanitarium and medical director of the Cape Sanitarium in Capetown, South Africa; formerly superintendent of St. Helena (Calif.) Sanitarium; since 1915 chief of the surgical staff of the White Memorial Hospital and served in a similar capacity at the Los Angeles County Hospital; consulting surgeon to the Southern Pacific Railroad Company, the Glendale and Loma Linda Sanitariums and the Los Angeles Police Department; died March 10, aged 74, of cerebral hemorrhage.

Frederick Manwaring Law ⊕ New York; University of Pennsylvania Department of Medicine, Philadelphia, 1901; specialist certified by the American Board of Otolaryngology and the American Board of Radiology; past president of the New York Roentgen Society; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otological Society, American Roentgen Ray Society and the American College of Radiology; served during World War I; consultant, Flushing (N. Y.) Hospital; on the staff of the Manhattan Eye, Ear and Throat Hospital; author of volume one, "Annals of Roentgenology," entitled "Mastoids Roentgenologically Considered"; died February 12, aged 71, of amyotrophic lateral sclerosis.

James Charles Boland, Binghamton, N. Y.; born in Troy, N. Y., on March 24, 1908; Albany (N. Y.) Medical College, 1932; member of the American Medical Association; since Nov. 1, 1946 deputy health commissioner of Rensselaer County; formerly health officer of Troy; served as assistant state health officer in the Binghamton district; for a short time acting commissioner of health for Columbia County; diplomate of the National Board of Medical Examiners; interned at the Troy (N. Y.) Hospital, where he had been resident physician and an associate physician on the staff; served as associate in venereal disease work at the Convent of the Good Shepherd in Troy; died February 18, aged 38, of chronic valvular heart disease.

Elbert Gleanard Wood ⊕ Knoxville, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1915; member of the House of Delegates of the American Medical Association from 1930 to 1946; served as president of the Tennessee Valley Medical Association; past president of the Knoxville Academy of Medicine; member of the Southeastern Surgical Congress; fellow of the International College of Surgeons; member and past chief of staff, Knoxville General and Fort Sanders hospitals; on the staff of St. Mary's Hospital; died March 10, aged 56, of cerebral hemorrhage.

Thomas Moore Dorbandt, San Antonio, Texas; Missouri Medical College, St. Louis, 1898; member of the American Medical Association and in 1926 member of the House of Delegates; member of the Southern Psychiatric Association, serving as its president and district counselor; member of the Bexar County Tuberculosis Association; past president of the Bexar County Medical Society; served as chairman of the local board of health, county physician and local surgeon for the Gulf, Colorado and Santa Fe Railway; died recently, aged 75, of cerebral hemorrhage and arteriosclerosis.

Ira Wall Ellis, Monette, Ark.; Memphis (Tenn.) Hospital Medical College, 1912; member of the American Medical Association; past president of the Craighead-Poinsett County Medical Society and the First Councilor District Medical Society; served as vice president of the Mid-South Postgraduate Medical Assembly and of the Arkansas Medical Society; for many years member of the school board; served during World War I; major, medical reserve corps, not on active duty; died in St. Bernard's Hospital, Jonesboro, January 27, aged 59, of cerebral hemorrhage.

Nathan Ernest Beardsley, Redlands, Calif.; University of Buffalo School of Medicine, 1890; died February 15, aged 79, of angina pectoris.

Frederick M. Braning, Bonne Terre, Mo.; Barnes Medical College, St. Louis, 1900; died in Farmington February 18, aged 72, of pneumonia.

William Seddon Cox, West Point, Va.; University College of Medicine, Richmond, 1913; member of the American Medical Association; formerly member of the town council; director of the Citizens & Farmers Bank; died in the Johnston-Willis Hospital, Richmond, February 11, aged 60, of carcinoma of the lung.

Orazio Roger Cupolo, Utica, N. Y.; Regia Università degli Studi di Bologna Facoltà di Medicina e Chirurgia, Italy, 1936; served internships at the Faxton Hospital and the Utica General Hospital; member of the American Medical Association; died February 5, aged 38, of coronary thrombosis.

Harvey Kendall Dever, El Reno, Okla.; University of Kansas School of Medicine, Kansas City, 1930; member of the American Medical Association; interned at the Montreal General Hospital in Montreal, Que., Canada; affiliated with the El Reno Sanitarium; assistant surgeon for the Rock Island Railroad; died in a local hospital February 1, aged 40, of coronary thrombosis.

Harrison Albert Dunn, Erie, Pa.; Jefferson Medical College of Philadelphia, 1905; died recently, aged 66, of congestive heart disease.

Herbert Renner Goshorn, Humboldt, Kan.; University Medical College of Kansas City, 1906; member of the American Medical Association; formerly affiliated with the Indian Service; died in the Johnson Hospital, Chanute, February 11, aged 69, of cerebral hemorrhage.

Joseph Thomas Gunter ⊕ Goliad, Texas; Chattanooga (Tenn.) Medical College, 1903; served during World War I; army surgeon of the Second Aero Provisional Regiment, occupying that post from the signing of the Armistice until March 1919; lieutenant colonel, medical reserve corps, not on active duty; died February 8, aged 71, of coronary thrombosis.

Eugene Andrew Hammond ⊕ New Berlin, N. Y.; Syracuse University College of Medicine, 1912; county coroner; health officer of New Berlin, Columbus and Pittsford; on the staffs of the Chenango Memorial Hospital, Norwich, and the Faxton Memorial Hospital in Utica; died in the Binghamton (N. Y.) City Hospital February 12, aged 58, of hypertensive cardiovascular disease and pneumonia.

Wiley Junior Jinkins, Galveston, Texas; University of Texas School of Medicine, Galveston, 1911; member of the American Medical Association; fellow of the American College of Surgeons; honorary member of the State Medical Association of Texas; past president of the Galveston County Medical Society; affiliated with the John Sealy Hospital and St. Mary's Infirmary; for many years director of the United States National Bank; died recently, aged 59, of heart disease while on a hunting trip near Columbus.

Hans Edgar Kudlich, New York; Columbia University College of Physicians and Surgeons, New York, 1904; member of the American Medical Association; for many years affiliated with the Lenox Hill Hospital; died February 20, aged 67, of coronary thrombosis.

Henry Bruce Landis, Broken Bow, Neb.; Central Medical College of St. Joseph, Mo., 1896; died in Lincoln February 3, aged 72, of paralysis agitans.

William Richard Leahy, San Francisco; John A. Creighton Medical College, Omaha, 1916; served with the U. S. Public Health Service reserve and Veterans Administration; lieutenant colonel, medical corps, Army of the United States, not on active duty; died recently, aged 54.

Isaac Roentgen Liberson, New York; Long Island College of Medicine, Brooklyn, 1945; interned at the Morrisania City Hospital; served a residency at the Goldwater Memorial Hospital; diplomate of the National Board of Medical Examiners; died recently, aged 23.

Edward Lynch Mathias ⊕ Kansas City, Mo.; University of Maryland School of Medicine, Baltimore, 1904; served during World War I; affiliated with St. Mary's Hospital, where he died February 3, aged 67, of coronary thrombosis.

William H. Moore, Fort Stockton, Texas; University of Texas School of Medicine, Galveston, 1903; for many years county health officer; local assistant surgeon for the Southern Pacific, International and Great Northern and Houston and Texas Central railways; died recently, aged 66, of bronchogenic cancer.

Daniel E. Murphy, Chicago; Northwestern University Medical School, Chicago, 1901; member of the American Medical Association; formerly assistant clinical professor of surgery at the Loyola University School of Medicine; served on the staff of the Alexian Brothers Hospital, where he died March 21, aged 77.

Willis F. Pierce, Los Angeles; Rush Medical College, Chicago, 1876; died January 15, aged 93, of chronic myocarditis.

Charles Eder Reed, Washington, D. C.; Columbian University Medical Department, Washington, D. C, 1903; died in the Garfield Memorial Hospital February 16, aged 72, of cardiac tamponade.

Adam William Reier ⊕ Dundalk, Md; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1916; past president of the Baltimore County Medical Society, Confrere Medical Club and the Dundalk Rotary Club; served overseas with the American Expeditionary Forces during World War I; charter member and member of the board of management of the Y. M. C. A.; died in the University of Maryland Hospital, Baltimore, March 10, aged 58, of coronary thrombosis.

Travis D. Rudd, Hopkinsville, Ky.; Kentucky School of Medicine, Louisville, 1896; died March 13, aged 79, of angina pectoris.

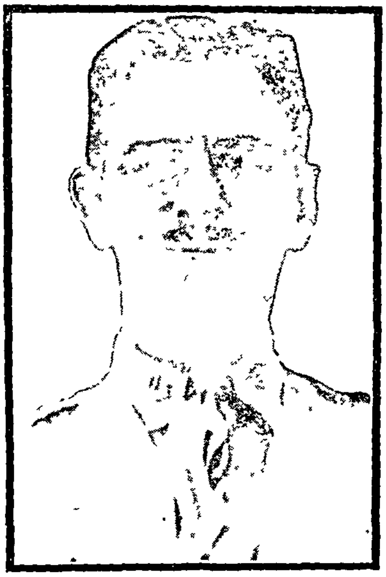
George H. Schenck, Southampton, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1904; member of the American Medical Association; for many years affiliated with the Southampton Hospital; died March 5, aged 67, of hypertensive heart disease.

Percy C. Waller Templeton ⊕ Irasburg, Vt.; Baltimore Medical College, 1904; health officer for the town for many years; on the executive board of the Orleans County Memorial Hospital in Newport at the time of his death, March 2, aged 67, of acute arthritis and malnutrition.

Mary Jane Walters, Marietta, Ga.; University of Pennsylvania School of Medicine, Philadelphia, 1929; member of the Medical Society of the State of Pennsylvania; served during World War II; at one time affiliated with Vassar College in Poughkeepsie and the State Hospital in Norristown, Pa.; on the staff of the Lawson Veterans Administration Hospital in Atlanta, where she died March 7, aged 53, of cancer.

John R. Williams, El Dorado Springs, Mo.; American Medical College, St. Louis, 1898; member of the American Medical Association; member and past president of the Vernon-Cedar Counties Medical Society; died recently, aged 75, of heart disease.

Joseph Mason Yater, Nevada, Mo.; Marion-Sims College of Medicine, St. Louis, 1901; member of the American Medical Association; on the staff of the Nevada Hospital; division surgeon for the Missouri Pacific and Missouri, Kansas and Texas Railroad companies; served as a member of the school board; died February 6, aged 79, of congestive heart failure.



Capt. Elliot A. Hayden
M. C., A. U. S., 1912-1944

Lieut. Francis C. Robinson
(MC), U. S. N. R., 1915-1946

Lieut. Maurice N. Manning
(MC), U. S. N, R., 1914-1945

KILLED IN ACTION

Elliot Alexander Hayden, New York; Universitat Basel Medizinische Fakultat, Switzerland, 1936; interned at the Jewish Memorial Hospital; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army in August 1940; promoted to captain; drowned in the South China Sea Oct. 24, 1944, aged 32, when the Japanese ship on which he was being transported while a prisoner of war was sunk.

Francis Clay Robinson, Grafton, W. Va.; Harvard Medical School, Boston, 1941; served a residency at the Cape Cod Hospital in Hyannis, Mass.; served an internship and residency at Worcester City Hospital in Worcester, Mass.; entered the medical corps of the U. S. Naval Reserve as a lieutenant (jg) in 1943; promoted to lieutenant; served with the 133d Naval Construction Battalion until October 1944; transferred to training with the Fourth Marine Division; first official notice in April 1945 stated wounded in action, presumably at Iwo Jima, and second official notice in June 1945 missing in action; presumed dead March 20, 1946, aged 29, by the U. S. Navy Department.

Maurice Norman Manning, Beaverton, Ore.; Yale University School of Medicine, New Haven, Conn, 1942; interned at the San Diego County General Hospital; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve; promoted to lieutenant; aged 31; killed May 18, 1945, while on the U. S. destroyer *Longshaw,* which ran aground at Okinawa and while under heavy fire from Japanese shore batteries, was hit in the ammunition stores and exploded.

LONDON

(From Our Regular Correspondent)

April 19, 1947.

A Cerebral Palsy Unit

The cerebral palsy unit, the first to be established in this country, set up in 1943 at Queen Mary's Hospital for Children, Carlshalton, for the treatment by the methods of Professor Phelps of Baltimore, has been treating an average of 14 children at a time. It is now proposed to enlarge the unit to take 20 at a time and later 40 and still later 60. A report by the Hospitals and Medical Services Committee of the London County Council shows that the Phelps method gives good results. Some hopelessly crippled children have been rendered capable of taking part in the life of at least a school for physically defective children and in many cases in a normal school life. The facilities for the treatment are therefore to be extended as quickly as possible. Both the Ministry of Health and the Ministry of Education want the work to be developed. The latter has appointed a technical adviser, who has visited America to study the methods employed there and the results achieved. A close association has been developed with a new school for children suffering from cerebral palsy which has been established by a voluntary organization. The staff of the unit includes a part time consulting physician and an orthopedic surgeon.

Penicillin in the Mouth

At the Section of Odontology of the Royal Society of Medicine Dr. Alexander MacGregor opened a discussion on local penicillin in the mouth. He said that the action appeared to be greatest in the first quarter of an hour. The speed of diffusion of penicillin was an advantage in the odontologic field because the drug could reach areas such as gum pockets quickly, but there was the disadvantage that the penicillin was rapidly lost. He used penicillin pastilles to get a slower action. Other methods were penicillin powder for insufflating cavities, cream, as to the advantages of which he was uncertain, and the most recent method of using cones with a fatty base.

A main indication for local penicillin in the mouth was Vincent's disease. In the acute form penicillin was the best treatment, but in the chronic form it was unavailing. There was usually some focus of infection, such as an impacted wisdom tooth, which must be eliminated or recurrence was likely. In ulcers of the mouth the results were mixed. In extractions, operations on cysts and gingivectomies penicillin was of advantage in obtaining a clean field.

The Hunterian Specimens at the Royal College of Surgeons

In his Hunterian Oration, delivered at the Royal College of Surgeons, Sir James Walton took for his subject "Hunterian Ideals Today." He said that only by the closest study of Hunter's specimens and his series could an appreciation of the importance and value of his work be obtained. It was a great satisfaction to know that in the Royal College of Surgeons his work was continued with unabated zeal. The great curators William Clift, Richard Owen, Sir Arthur Keith and today Professor Wood Jones had all been ardent followers of Hunter, and in their hands the museum had grown and developed. Before the war Hunter's museum had been the Mecca of all surgeons. It had suffered grievous loss from German bombing. Some of Hunter's specimens had lost their value because of destruction of his manuscripts. But sufficient Hunterian specimens were left to form a nucleus, and all would agree with the decision of the council of the college not to separate them as a historical group but to have them as a living center of growth in each section.

TURKEY

(From Our Regular Correspondent)

ANKARA, March 10, 1947.

Public Health During World War II

During the six years of war public health work has continued. Turkey, though not entering the war as a belligerent, was obliged to keep under arms an army of about a million to guard her European and Asiatic frontiers. In large cities such foods as bread, fats, meat, sugar and rice had to be rationed. There was also a shortage of coal. Sugar, which before the war cost 32 kuruş a kilogram, rose to 645 kuruş, with the result that many people had to go without it. Farmers suffered less. They sold their products well, and they use grape treacle and honey instead of sugar. People in cities in the lower income groups suffered most, and tuberculosis increased considerably. During 1940-1941 there was an outbreak of smallpox among refugees from Persia and Iraq and then in the Eastern and Southeastern provinces, but systematic vaccination prevented the spread and today there is not a case of smallpox in the country. During 1942-1943 there was an outbreak of malaria for which heavy rainfalls and an insufficiency of crude oil and quinine were responsible; with the help of great quantities of American quinacrine the outbreak was overcome. The typhus epidemic was checked first with American and then with Turkish DDT, and preventive measures in regard to lice. Typhus vaccination has been resorted to since 1944. Syphilis took its normal course, as did other communicable diseases such as scarlet fever, meningitis, measles, chickenpox and diphtheria. With the aid of sulfonamides infant mortality due to summer diarrhea was kept at a low level. A few cases of recurrent fever, of which not 1 case is on record during the six war years, have occurred recently among refugees from Persia with 27 cases, but the outbreak was soon taken care of. There are now eighty-four antirabic treatment centers where patients are treated by the Semple method, resulting in a steady decrease of hydrophobia.

The Central Institute of Hygiene in Ankara has continued to prepare and deliver all vaccines and serums during the whole period of the war. And though their turn to serve in the army came around two or three times to many general practitioners, to specialists in institutions and private practice, as well as to health officers and chemists, this has not been to the detriment of the civilian population owing to systematic rotation of service.

During the war the marriage rate took its normal course, in urban communities 12-20 and in rural communities 25-30 per thousand. The birth rate showed a mild decline in rural communities because of the fact that almost a million men were kept under arms, though in rural communities the birth rate was 35 to 40 per thousand. The general death rate in urban communities was 18 to 22 per thousand. The earthquake that took place in December 1939 in the eastern province of Erzindjan was responsible for the sudden death of more than 32,000 persons.

Increase in Population

The first census in Turkey was taken in October 1927. The population then was 13,648,270, of which 6,563,879 were males and 7,084,391 females. Turkey then had 762,736 square kilometers. Of the inhabitants 1,040,669 were living in the European part of Turkey and 12,607,601 in Anatolia. Of the three largest cities, Istanbul had a population of 690,657, Smyrna (Izmir) 153,924 and Ankara 74,553.

The second census was taken in 1935. The population had increased to 16,158,018, of which 7,936,770 were males and 8,221,248 females. The next year the annexation of the province of Hatay from Syria added an estimated population of 273,350. With Hatay included, Turkey has now 767,943 square kilometers with a density of 21 persons per square kilometer. There were then thirty-two cities with a population of 10,001-15,000, eleven with 15,001-20,000, sixteen with 20,001-25,000 and fourteen with 25,001-50,000. Four cities had a population of 50,001-100,000.

Of these, three cities Istanbul had 741,148, Izmir 170,959 and Ankara 122,701 inhabitants.

The third census, taken in October 1940, showed that Turkey's population was 17,858,164, of which 8,940,178 were males and 8,917,986 females. According to the fourth and last census, taken in October 1945, Turkey's population is 18,859,722. Istanbul has a population of 844,090, Ankara 227,505 and Izmir 201,088, with 24 persons per square kilometer.

In 1923 the exchange of population after the Lausanne treaty brought 196,420 Turks from Greece to Turkey, adding in 1924 another 208,886. After 1924 not more than 50,729 persons a year have entered Turkey as refugee immigrants; all are Turks from Bulgaria, Rumania and Yugoslavia. The outbreak of the second world war temporarily ended emigration from these countries; it is expected that in the near future more than a million Turks will want to immigrate into Turkey.

MOSCOW

Private Medical Practice in Russia

Private practice in our country is not a problem for young physicians for the following reasons:

The demand for staff personnel in medical establishments where aid is free of charge is always greater than the supply. The number of ambulatories, hospitals, kindergartens and maternity houses constantly increase. To meet the demand for physicians and to guarantee employment to medical students after graduating, medical schools have a planned quota of students. The enrolment plans per annum are based on the five year program whereby some 100,000 physicians are to be trained. Prior to World War II the total of physicians in the Soviet Union exceeded 150,000, almost eight times their number in tsarist Russia.

Private medical practice exists in our country, but it can neither be bought nor sold as this is done abroad; practice is acquired as a result of the reputation the doctor earns in the course of his work. Any physician can conduct practice at home; this is recognized by the Soviet laws. All doctors are obliged to keep a record of their patients in a ledger where the case history and treatment are recorded, and they must follow all sanitary and hygienic regulations in private practice (according to the law "On Professional Work and Rights of Medical Workers"). Systematic medical inspection insures the observance of this law.

Volatile Vitamins

Professor M. Maisel and his collaborators at the Microbiologic Institute of the U. S. S. R. Academy of Science confirmed the hypothesis of Academician N. Kholodny (Academy of Science of the Ukrainian S. S. R.) that in growing plants such as peas a number of volatile vitamins—thiamine, pyridoxine, nicotinic acid and para-aminobenzoic acid—are present. Coming in through air they act on micro-organisms in the same way as when added to nutritive medium in liquid or powder form. This property was discovered when vitamin contents were tested in foods.

At present volatile vitamins are added to nutritive mediums which activate the growth of micro-organisms. Some of them, as yeast and yeastlike fungi, in absence of vitamins demonstrate symptoms of avitaminosis, observed as disturbance of fermentation processes, cell infiltration and others. When Petri dishes with yeast cultures with and without vitamins stood side by side, volatility of vitamins could be registered by many of the aforementioned signs. If the Petri dishes were placed in different rooms the volatility was not observed and signs of avitaminosis developed. This has a practical meaning, permitting the establishment of the quantity of niacin, thiamine, pyridoxine and other vitamins in food and plants even in very small quantities.

Problems of Neurosurgery

Hypertension and the results of war injuries of the peripheral nervous system were the principal questions discussed at the Leningrad session of the All-Union Neurosurgical Council and the Leningrad Institute of Neurosurgery. V. N. Shevkunenko in his paper on the peripheral part of the vegetative nervous system confirmed the existence of intersegmentary correlations. They guarantee the mobility of vegetative reactions and thus aggravate surgical intervention on separate parts of the vegetative system. Ganglionectomy may be performed only if the local blockade does not give gratifying results.

One of the leaders of the Leningrad school, G. F. Lang, stated that operations performed on the sympathetic nervous system are most effective for the treatment of hypertension. They alleviate headache, improve vision, restore physical activity and cause temporary diminution of blood pressure. Conservative therapy is effective only in an early neurogenic stage. Soviet surgeons, contrary to their American colleagues, are not enthusiastic for surgical intervention for hypertension.

P. K. Anokhin demonstrated that under the influence of psychic irritation depressor nerve function ceases and hypertension progresses.

Professor A. L. Polenov and dozent A. V. Bondarchuk reported their observations on 18 operations for hypertension on the sympathetic nervous system. They ascertained that mechanical irritation of the semilunar ganglions raises blood pressure, while section of vagal branches that come close to them is accompanied with fall of the tension. A bilateral blockade of the sixth to ninth thoracic ganglions diminishes tension by 15-25 mm. of mercury. Desympathization gives a steady fall in blood pressure if the elasticity of the vessel wall and regulative properties of the endocrine and vegetative system are maintained. The therapeutic effect of operations on the sympathetic nervous system results in improvement of vision and hearing, decrease of muscular rigidity and restitution of movements of injured extremities. The existence of the third and fourth degrees of hypertensive disease (by Smithwick) as well as essential hypertension is a contraindication for surgical intervention.

Professor T. M. Lampert described his new method for surgical treatment of hypertensive diseases. It consists in removal of the solar plexus, desympathization of the renal pelvis and renal decapsulation. Thus adrenal denervation is obtained and excretion of epinephrine and secretin is decreased. This method was used by Lampert in 13 cases. In 10 cases, of which 4 were bilateral, he obtained good results. Three cases with advanced nephrosclerosis ended fatally.

Dozent A. S. Lourje reported the transposition of the ulnar and radial nerves from the plantar to the palmar surface and on the implantation of healthy nerve in an injured one. This permits surgeons to use nerve transplantation less often even in difficult cases. Professor G. A. Richter spoke about his method of rational section directly over the operated nerve, preventing cicatrix formation. This method received approval in the American medical literature.

Professor D. G. Schaefer, V. A. Goichman and others spoke on remote results of neurosurgical treatment. According to Goichman's data, after two years the operation of neurolysis gave much improvement in 94.4 per cent and that of nerve suture in 61 per cent (of 219 cases) if the operation was made within two to ten weeks after the injury. Schaefer, on the contrary, maintains that better results are obtained if surgical intervention is performed after a period of five to six months after injury.

V. V. Troitzky cultivated the nerve end in ether-caoutchouc solution. The special rubber cap which is thus formed becomes an obstacle hindering axon cylinders coming out into the wound and thus not permitting phantom pains to develop.

Correspondence

REACTIONS TO INFLUENZA VIRUS VACCINES

To the Editor:—In Dr. Curphey's article in THE JOURNAL, April 12, concerning a fatal reaction to influenza virus vaccine he has apparently utilized the occurrence of a fatal case in a 3½ year old child to emphasize the work of Ratner and Untracht (THE JOURNAL, Dec. 14, 1946, p. 899) regarding the advisability of determining the existence of egg allergy before using vaccines of egg origin.

There are so many features about Dr. Curphey's case that are not compatible with an allergic reaction that one might question, as Dr. Curphey has done, the mechanism he emphasized as probably responsible for the course of events observed. If, as seems possible, the reaction that occurred was not due to egg allergy, the results of a skin test would not have provided information that could have prevented the fatal reaction.

Therefore I should like to take the opportunity to call attention to one of the constituents of the vaccine that might, more likely, have been the offending component in the case that was described. The component to which I refer is the virus itself. The part played by the virus, rather than the nonvirus proteins, in reactions to influenza vaccine has been mentioned in various publications. The detailed data on this point are the subject of a report soon to be published. In the latter investigation it was found that "toxic" reactions to the vaccine are proportional in frequency and severity to the concentration of virus injected. Moreover, these reactions are uninfluenced by the small amount of extraneous protein present in the materials of various degrees of purity that were tested.

The more severe reactions that were observed in adults given rather large doses of virus concentrated and purified by differential centrifugation frequently began four to five hours after injection, a time of onset similar to that in the case described by Dr. Curphey. The symptoms and signs of reaction were chills, fever up to 103 F. recorded orally, severe headache, vomiting, agitation and anxiety; body aches and varying degrees of prostration also occurred. In a few cases, in these experimental studies with large doses, the reactions were somewhat alarming.

In a limited experience with young infants and children, reactions of greater severity, accompanied with higher temperatures, could be produced by considerably smaller doses of virus.

Therefore it would seem that if Dr. Curphey's case was a toxic reaction to some "foreign protein," as he suggested alternatively in his comments, and if the "foreign protein" was the virus itself, as the foregoing remarks suggest, a skin test for egg sensitivity would not have foreshadowed the course of events that followed the inoculation.

If the reaction is in the nature of a toxic reaction to the virus —and the findings in Dr. Curphey's case appear to me more compatible with this view than with the view that it was due to an asymptomatic allergy to some egg constituent in the vaccine—and since the frequency and severity of reactions are related to virus concentration, it would seem reasonable to consider a reduction in the concentration of virus in vaccines for use in children, at least, to levels that do not produce the undesirable effects or that much smaller doses be employed. The importance of the factor of age in relation to the severity of reaction is indicated in Dr. Curphey's report, in which he noted that reactions had occurred in all 3 children who were inoculated. The mechanism of the reaction was probably the same in the 3 children but differed in severity, depending on age.

In the study of reactions to be published, it was found that the dose of virus can be varied over a rather wide range with little influence on mean antibody response in groups given different doses. This was in contrast to the narrower range of dosage, over which there occurs a sharp increase in frequency and severity of reactions. Thus it appears that the dose of virus for vaccination could be safely adjusted to subreactive levels without significantly reducing antibody inducing effect. In children, especially, the quantity of antigen administered can be reduced considerably and still be effective in inducing a good antibody response.

For the present, therefore, it might be suggested that caution be exercised in the use of influenza vaccines not only with respect to sensitivity to egg constituents but with respect to the dose of virus given to young children. Until definitive studies are reported it would seem advisable to reduce the dose for children proportionately more than would be suggested on the basis of size in comparison with the adult.

CHANGES IN MOUTH TISSUES AFTER VACCINATION

To the Editor:—A clinical observation which I believe has not been reported before is especially timely in view of the present drive for universal revaccination initiated by Commissioner Israel Weinstein of New York City.

I have had several cases for diagnosis of a painful itching or burning in discrete circumscribed areas in various parts of the mouth (tongue, lips, gingivae) which clinically show slight edema or desquamation. These lesions appear three to four days after vaccination against smallpox with varying intensity. No doubt the majority of the patients report no symptoms of this type, but for those who are affected the diagnosis may have puzzled some.

It is possible that other forms of immunization may produce temporary aberrations of the oral tissues which previously have not been thus associated.

SAMUEL CHARLES MILLER, D.D.S., New York.
Associate Professor and Chairman of the Periodontia Department, New York University College of Dentistry.

PSYCHOSOMATIC HOMEOSTASIS

To the Editor:—When Dr. W. C. Menninger delivered the second Menas K. Gregory Lecture before the Psychiatric Division of Bellevue Hospital, he said, in part, that the "universality of emotions, of feelings and their effects on the human body make it imperative that every individual practicing medicine be as well grounded in the anatomy, physiology and pathology of the psyche as he is in that of the soma" (Lessons from Military Psychiatry for Civilian Psychiatry, *Diplomate* **19**:69, 1947). As if replying in rebuttal, Wilson and Rupp observed somewhat later as they surveyed the present trends in neurology that "save for a few isolated exceptions, most of the psychosomaticists have become too preoccupied with aspects of the psyche to the neglect of the soma" (Present Trends in the Practice of Neurology, THE JOURNAL, Feb. 22, 1947, p. 509). This parallelism of verbal expression presents a provoking divergence of emphasis.

The psychosomatic approach to medicine is a synergism of the psychologic and the physiologic approaches to diagnosis and treatment; to assume that either approach is the figurative host and the other, therefore, the parasite is as fallacious as it is unsound and as unsound as it is clinically misleading. There is no "either or" about psychosomatic thinking; every patient presents both components. If, in some, one aspect is hypertrophied and the other relatively atrophied, both are invariably present if sought and recognized.

The literature of late has become saturated with reports depicting the miraculous success obtained by the application of psychologic thinking to unsuccessful solutions of perplexing problems which have run the gantlet of medical diagnostic and therapeutic measures. Apparently, these authors attempt to convey the point of view that the psyche is more powerful than the sword and, for that matter, more powerful than the scalpel and the stethoscope as well. It has become a pet diversion of psychiatrists and psychosomatists to collect medical and surgical failures and by application of psychiatric methods, orthodox or otherwise, to convert these traumatized patients into living singing commercials for psychosomatism. This is reminiscent of the chiropractor and his back breaking success with alleged medical failures. It is with this preponderance of emphasis on the psyche that one may reasonably take to task the school of medical thinking. On the other hand, many internists and surgeons (in fact none of the somatic specialists are innocent of this ignominious pastime) enjoy nothing more than finding a tangibly organic basis for some hazy psychologic syndrome which has been irradiated only with unsuccessful psychotherapy. To an equal extent, these somatists are poorly oriented.

An erroneous interpretation of the point of view presented may reasonably be suggested. No blow is being struck at psychosomatism, nor is an attempt being made to create a medical red herring. The sole concern is with advocating that practitioners maintain a diagnostic and therapeutic homeostasis between the psyche and the soma. Whether, as Portis suggests (The Medical Treatment of Psychosomatic Disturbances, The Journal, Oct. 14, 1944, p. 413), emotional stimuli produce disturbed function, and disturbed function ultimately results in pathologic change, is not contraverted here. It may well be also that the treatment of pathologic change may be medical or surgical, but the fundamental etiologic approach and prevention of recurrence depends on a study and normalization of the emotional status. This hypothesis too is not at present a question of discussion. What is questioned, however, is the doubtful appreciation in practice (if not in theory) by medical practitioners of the dynamic equilibrium between the psyche and the soma. Each clinician must maintain a psychosomatic homeostasis if he is to evaluate correctly the relation of psychologic and physiologic pathologic changes presented in the patient.

TRANSMISSION OF BRUCELLA IN MILK

To the Editor:—I have read with considerable interest the questions and answers in Queries and Minor Notes in the April 5 issue of The Journal on Transmission of Brucella in Milk.

From epidemiologic, laboratory and experimental studies in Iowa it is quite obvious that contact with infected animals plays a more important role than does the use of contaminated raw milk supplies. Where organisms of the Brucella group were isolated from human beings in Iowa, the greater share were from men such as farmers, veterinarians and packing plant workers handling infected animals, and the species of Brucella isolated were rarely of the abortus type. On the contrary the abortus species was found in most instances among farm women, young children and city folk, who rarely handle infected animals. Thus we have two distinct routes of infection—infection by way of the skin and by ingestion. From the experimental work with guinea pigs, Hardy and his associates showed definitely how the skin is a more potential route of infection than is the ingestion route (Hardy, A. V.; Hudson, M. G., and Jordan, C. F.: The Skin as a Portal of Entry in Brucella Melitensis Infections, *J. Infect. Dis.* **45**:271 [Oct.] 1929). To April 1, 1947 420 strains of Brucella have been isolated in the State Hygienic Laboratory from human beings of which 259 were of Brucella suis, 112 Brucella abortus and 49 Brucella melitensis. So far we have not found cattle in Iowa infected with Brucella melitensis, the human infections apparently coming from contact with hogs which were found infected with this species.

Pasteurization, if carried out properly, is effective in destroying all three species of Brucella. While I was investigating an outbreak of disease in a guinea pig herd it was found that the animals had been fed with pasteurized milk. A check of the pasteurizing plant revealed that the usual standards for pasteurization were not being effectively carried out. Brucella suis was isolated from the guinea pigs and the inadequately pasteurized milk.

Although adequate pasteurization of milk and dairy products is effective in controlling brucellosis from those sources, more emphasis must be directed toward the control of the disease in hogs, which in the Midwest are the source of a greater share of brucellosis in man.

Further epidemiologic data to bring out these points will be found in the *American Journal of Medicine* **2**:156 (Feb.) 1947.

Director, State Hygienic Laboratory.

ENDOCRINE TREATMENT OF MALE STERILITY

To the Editor:—In the January 18 issue of The Journal Dr. Abner I. Weisman indicated in a communication to the editor that no endocrine therapy was of any value in the treatment of male sterility. This nihilistic point of view leaves no encouragement for physicians' treating sterility when the male is involved and apparently means that a low semen count in a man is of no more importance than to indicate a hopeless outlook for the involved individual.

On the contrary, it has been my experience in treating or supervising the treatment of between 75 and 100 men with relative sterility that there are definite hormones that will raise the sperm count to normal in more than half of the patients. The very low sperm counts of less than 10 million and particularly around 1 or 2 million are rarely improved, but in the majority of patients with relative sterility having counts varying from 10 to 60 million very encouraging results have been obtained. If the patient is hypothyroid, as shown by the basal metabolism or clinical appearance, thyroid may be followed by extraordinary improvement. If the patient is not hypothyroid or is somewhat hyperthyroid the giving of additional thyroid is of no value. Secondly, the use of equine gonadotropin (used in my experience as gonadogen, Upjohn) in doses of 20 units, three times weekly, subcutaneously, has been followed many times by remarkable changes in the sperm count. In the past five years also all of my patients have received large doses of vitamin C, although the evidence that this is of definite value is by no means clear; but certainly it does no harm. Courses of treatment are given continuously with repeated semen analyses after each four weeks.

In the face of such a depressing outlook this constructive therapy is offered as being of definite value in a majority of cases.

My first report was made in 1942 (Clinical Evaluation of Equine Gonadotropin, *Am. J. Obst. & Gynec.* **43**:387 [March] 1942).

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Constitutionality of Provision Relating to Appointment of Medical Commission.—The plaintiff filed a claim for disability compensation allegedly resulting from an occupational disease contracted in the course of his employment with the Ford Motor Company. From a denial of his claim, the plaintiff appealed to the Supreme Court of Michigan.

Prior to August 1943 the plaintiff had worked for the defendant for about twenty years, almost the entire period of which was spent in the defendant's millwright department. On that date he quit his employment because of his physical condition. His claim for compensation alleged that during the period of his employment he was exposed to dust and that he became disabled by reason of "pneumoconiosis, possibly complicated by sequelae such as tuberculosis."

Section 6 of the workmen's compensation act, which was added to the law in 1937, provides: "In case the employe is alleged to be suffering from an occupational disease and there shall be a dispute with respect thereto, the said board, or any member thereof, shall appoint a commission of three qualified impartial physicians to examine the injured employe and to report. The report, when signed by at least two of the members of said commission, shall be final and conclusive as to the condition of said employe with respect to the alleged disease or diseases. . . ."

Pursuant to this section, and at the request of the defendant, a medical commission was appointed which filed a report based on an examination of the plaintiff made on Jan. 3, 1945. The report stated that the plaintiff did not have pneumoconiosis on that date but that he did have x-ray and clinical evidence of tuberculosis. The department denied the plaintiff's claim on the theory that if the claimant did not have pneumoconiosis in 1945 he had not had it at any time during the prior period for which disability was claimed. On appeal, the plaintiff contended that section 6 violated the "due process" clause of both the state and federal constitutions. Emphasis was placed on the failure of the statute to give the parties in interest the right to appear before the medical commission and present evidence, and it was insisted that such failure deprives the parties of a right to a full and fair hearing and prevented the introduction of rebuttal proofs. Attention was called to the requirement that the department of labor and industry accept the report as final as to the condition of the employee on the date of the examination, without opportunity to consider the proofs presented to the medical commission, and to the fact that the court, in reviewing the department's action, could not have such proofs before it. Summarizing his contentions, the plaintiff's attorney stated: "We maintain that the appointment of a medical commission in this state is unconstitutional because it deprives the litigant of a right to a proper hearing of the issues in his case and of judicial review of the reasonableness of the determination by an administrative board."

The attorney general, in a brief filed at the court's request, agreed with the plaintiff that the procedure with reference to the medical commission is not in accord with fundamental principles of "due process of law." In support of his contention counsel for plaintiff called attention to the decision of the Supreme Court of Minnesota in *Hunter* v. *Zenith Bridge Co.*, 19 N. W. (2d) 795. In that case a provision of the Minnesota workmen's compensation act, analogous to section 6 of the Michigan act, was held unconstitutional. The Minnesota provision gave to the medical board the right to examine witnesses and required that it file its findings with the commission, including therein the names of doctors appearing and also medical reports and exhibits considered. No provision was made, however, for filing a transcript of the evidence on which the board based its determination. During the course of its opinion, the Supreme Court of Minnesota said "It is our opinion that because the delegation of power to the medical board here in effect denied relator and other claimants under the occupational diseases provision of the workmen's compensation law an effective right of review or appeal as prescribed by said workmen's compensation act, as well as under the due process guaranties of both the state and federal constitutions, the statute insofar as it creates said medical board and sets forth its functions constitutes an invasion of rights protected and guaranteed by said constitutions and is therefore null and void." A prior Michigan case said "We have always held, under the workmen's compensation law, that the court will examine the record to determine whether there is any evidence to sustain the findings of fact made by the department of labor and industry . . ." and then it quoted from the Supreme Court of the United States and said "It is true that if a legislature attempts to make the findings of fact of its agencies conclusive, even though the findings are wrong and constitutional rights have been invaded, the legislative action is invalid, for the judicial power of the courts cannot thus be circumscribed."

On the basis of such decisions, the Supreme Court of Michigan said that section 6 of the Michigan workmen's compensation law was unconstitutional. Due process of law requires notice and an opportunity to be heard; it imports the right to a fair trial of the issues involved in the controversy and a determination of disputed questions of fact on the basis of evidence. Under section 6 of the workmen's compensation law no record is directed to be kept by the medical commission; only the conclusion reached need be submitted to the department of labor and industry. Neither employee nor employer is afforded an opportunity before the medical commission to explain or rebut the showing on which its conclusion is based. There is no requirement with reference to notice, and the right to a fair hearing is not safeguarded. Such rights are, however, guaranteed by both state and federal constitutions, the Supreme Court concluded.

Since the determination of the department was based on the report of the medical commission, the section dealing with which was held to be unconstitutional, the Supreme Court of Michigan reversed the judgment in favor of the defendant and remanded the case for further proceedings.—*Dation v. Ford Motor Co., 22 N. W. (2d) 252 (Mich., 1946).*

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, May 17, page 314.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Various centers, June 16-18. *Part III.* Various centers, June. Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: Part II. *Oral.* Cleveland, Oct. 5-11. Sec., Dr. P. M. Wood, 131 Riverside Dr., New York 24.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various Centers, Oct. 20. Final date for filing application is June 1. Asst. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Oral. Chicago, June 4-5. Sec., Dr. Paul C. Bucy, 912 S. Wood St., Chicago.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia; June 15-19. Chicago, October 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Part II. Chicago, Jan. *22-23.* Final date for filing applications is *Sept. 15, 1947.* Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

AMERICAN BOAR[illegible] Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, [illegible] City, Ia.

AMERICAN BOAR[illegible] Oct. 24-25. Final date for filing application is Sept. 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kings Highway, St. Louis 10.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in April and November of each year in the home town of applicants. Applications should be sent to Sec., Dr. Robert H. Ivy, c/o Clerical Secretary, 4647 Pershing Ave., St. Louis 8.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Final date for filing application is Sept. 15. Sec., Dr. Francis J. Braceland, 102-110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Oral.* Boston, Nov. 26-30. Sec., Dr. B. R. Kirklin, 102-110 Second Avenue, S. W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: Final date for filing application for the next written examination is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Plasma Substitutes. C. E. Koop.—p. 233.

Exophthalmos of Endocrine Origin. T. G. Martens.—p. 241.

Treatment of Macrocytic Anemia in Relapse.—Frommeyer and Spies report the results of treating 100 patients with concentrated liver extract, 24 patients treated with synthetic folic acid and 14 patients treated with synthetic 5-methyl uracil. These patients had either true addisonian pernicious anemia, nutritional macrocytic anemia or the macrocytic anemia of tropical sprue. The hematologic findings show that, under the conditions of the study and in the dosages used, each of these three substances causes a remission. The clinical and hematologic response to folic acid parallels that which occurs following concentrated liver extract therapy, but the rate of regeneration is greater with potent liver extract. The authors especially recommend folic acid when there is sensitivity to liver. Synthetic 5-methyl uracil is the least effective of the three substances. The rate of red cell rise and the peak attained is definitely of a lower order than that obtained with either synthetic folic acid or concentrated liver extract. While 5-methyl uracil is of great scientific interest, it has no practical therapeutic value at the dosage level required to maintain a normal red blood cell count. From these and other studies it seems to the authors that the active principle in liver extract is not folic acid but is a very powerful substance which, when obtained in pure form, probably will be no more efficacious per unit weight than is folic acid.

Effect of Patent Ductus Arteriosus on Body Growth.—Porter says that no factor other than the patent ductus could be found to account for the smallness of each of 3 patients, and, when the ductus was successfully closed in 1 he outstripped his twin in height in less than three years. In many patients the growth inhibiting factor is an added reason for surgical ligation of a patent ductus arteriosus. The optimum period for operation is probably before the age of 11 years.

Irradiation of Pituitary in Arterial Hypertension.—The 142 patients treated by Pendergrass and his associates were adults with arterial hypertension. This report is concerned chiefly with the 93 patients who were followed for from three to fifty-six months. About half of these persons showed improvement in blood pressure and clinical condition. All the patients were selected on the basis of a positive test for antidiuretic hormone in the serum. The chance of benefit from radiation therapy to the pituitary in hypertension should be at least 75 per cent if cases are selected according to these criteria: (1) positive bioassay for antidiuretic hormone in serum; (2) a dosage of 1,000 roentgens delivered into the hypophysis (2,000 roentgens in air), to be repeated in three months if the test for antidiuretic hormone in the serum has not become negative in that time; (3) a negative bioassay for gonadotropic hormone in serum; (4) a normal renal function; (5) good clearance of injected dye from each kidney, as shown by urography.

Vitamin A Treatment of Leukoplakia Vulvae.—Hyams and Bloom report 18 cases of minimal leukoplakia vulvae with mild degree of involvement in all of which the diagnosis has been verified by microscopic examination. In 10 cases little or no free hydrochloric acid was revealed on examination of the gastric contents, which anacidity is definitely abnormally high as compared to its normal physiologic incidence of 35 per cent for any similar age group. Clinical studies in other fields have demonstrated the relationship existing between gastric anacidity and the low plasma level of vitamin A. Vitamin A treatment was therefore begun with a daily oral dose varying from 250,000 units to 500,000 units, supplemented by injections of 50,000 units twice weekly. In addition, each patient received 1 cc. of diluted hydrochloric acid in water three times daily with each meal. Of the 18 patients treated, 14 have been relieved both subjectively and objectively. The 4 unimproved patients suffered from some constitutional disease. It is concluded that leukoplakia vulvae is of metabolic origin because of a failure in utilization and/or absorption of vitamin A. Uncomplicated cases of minimal leukoplakia can be relieved with adequate doses of vitamin A and diluted hydrochloric acid. In four years of observation not 1 case showed a tendency toward vulvar carcinoma. Leukoplakia is probably not a neoplastic disease.

Presacral Neurectomy in Dysmenorrhea.—Tucker reviews 255 cases of surgical removal of the superior hypogastric plexus or presacral nerve for dysmenorrhea of both the essential and the acquired type. A comparative study was made between the 136 operations performed from 1931 to 1940 and the 119 operations during the period of 1941 to 1945. Complete relief from what is commonly termed essential dysmenorrhea (cramps) was obtained in 78 per cent of cases. There was some degree of improvement of symptoms in an additional 11 per cent. Complete relief from acquired dysmenorrhea occurred in only 33⅓ per cent of cases. Total failure of the procedure was recorded in 11 per cent of the essential dysmenorrhea group, whereas this poor result was obtained in 41.7 per cent of the acquired dysmenorrhea group. It is pointed out that pelvic inflammation and endometriosis made up about 60 per cent of the acquired dysmenorrhea group; 21 per cent of cases in these two categories came to total hysterectomy nine months to four years after presacral neurectomy was performed. Presacral neurectomy is still a court of last resort in the treatment of dysmenorrhea. The operation carries with it the risk of laparotomy. Good medical management should be attempted in each individual case before resorting to surgery unless other indications for laparotomy exist.

Brucellosis in the United States.—Evans reviews the history of the recognition of brucellosis in the United States and shows that the disease is of considerable importance as a public health problem. She stresses that the prevalence of brucellosis in man depends on its prevalence in animals and that it is predominantly a rural disease. A fundamental problem of brucellosis is the discovery of methods for the control of the disease in animals. The discovery of an effective therapeutic agent is urgent from the point of view of both the human and the animal disease. The development of laboratory technics to facilitate the recognition of the mild form of the disease is important.

Scalenus Anticus Syndrome.—Patients with pain in the neck, shoulder, arm and forearm, with numbness and tingling in the thumb, index, ring or little fingers associated with muscle weakness, should have a thorough neurologic examination of the muscles and nerves of the involved extremity. The scalenus anticus muscle on the involved side is painful to palpation and pressure in all patients exhibiting the syndrome. If pain is not present on pressure over the lower portion of the scalenus anticus muscle, the patient probably does not have scalenus anticus syndrome. The condition must be differentiated from subacromial bursitis, brachial plexus neuritis, arthritis of the cervical spine, herniated cervical disk, rupture of the supraspinatus tendon, sympathalgia of the cervicodorsal type and cervical rib. The conservative treatment of scalenus anticus syndrome consists in correction of poor posture, massage, diathermy, rest of the upper extremity, injection of the scalenus anticus muscle with procaine hydrochloride and sleeping on three pillows. If conservative treatment fails, scalenotomy with partial resection of the scalenus anticus muscle is indicated.

Trauma in Malignant Bone Tumors.—Coley thinks that the role of a single injury in the development of bone sarcoma has been overemphasized. Considering the universality of injuries on a par with those alleged to be the cause of sarcoma of bone, it is difficult to explain why so few of them are followed by the development of sarcoma.

Human Glanders: Report of 6 Cases. C. Howe and W. R. Miller.—p. 93.

Surgical Treatment of Brochiectasis.—Kay and his associates base the opinions presented in this report on the treatment of 390 patients with bronchiectasis at the Chest Center and at Percy Jones General Hospital during the past three years.

During this period there have been 220 consecutive lobectomies with only one death The bronchiectasis in the patients not operated on was either too minimal, too patchy and diffuse or too extensive A small number of patients refused operation Postoperative bronchopleural fistula and empyema occurred in only 20 cases Pulmonary function as determined by bronchospirometric studies in a small group of patients preoperatively and postoperatively demonstrated that the oxygen consumption and ventilation within several months postoperatively were only slightly below normal values and in most cases either essentially the same or improved over preoperative levels

Late Residuals in Infectious Hepatitis.—Klatskin and Rappaport found that 108 of 217 patients who were considered fully recovered from acute infectious hepatitis had residuals evidenced by symptoms, hepatomegaly or impaired liver function for periods ranging up to twenty-seven years The only significant symptoms were fat intolerance and right upper quadrant pain These residuals indicated a disturbance of the liver, but the presence of structural changes was not established The residuals were compatible with good health and full activity over long periods of time The only factor which appeared to play a significant role in the incidence of residuals was the severity of the jaundice There was no evidence to indicate that the late residuals of infectious hepatitis progress to cirrhosis Coarse nodular cirrhosis does occur occasionally during the first six months of chronic progressive or recurrent infectious hepatitis

Protamine Zinc Insulin and Globin Insulin.—Roberts and Yater treated 84 patients with both globin and protamine zinc insulins, with blood sugar curves obtained while they were being given an equal dose of each form of insulin The authors gained the impression that both are satisfactory preparations in the treatment of a large percentage of diabetic patients Although each form is better than the other in some patients, more of them were controlled more satisfactorily with globin insulin Globin insulin controls the blood sugar curve and glycosuria in a more nearly normal way in more cases than an equal dose of protamine zinc insulin Globin insulin as now prepared with glycerin is free of significant local reactions or allergy The tendency to midafternoon hypoglycemia with globin insulin is preferable to nocturnal reactions, which are likely to be severe with protamine zinc insulin The majority of patients with diabetes who require insulin can be adequately controlled by a single dose of either globin insulin or protamine zinc insulin

*Abdominal Rigidity a Symptom *of Concussion of Spinal Cord* K *H* Abbott —p 220

Blood Flow Through Brain—Gibbs and his co-workers determined the blood flow through the human brain by injecting at constant rate a physiologically inert, nondiffusible substance into a major cerebral artery and then determining the concentration of that substance in a major cerebral venous channel The substance chosen for injection was Evans blue (T-1824) The cerebral blood flow was measured in 7 patients The average resting flow for all subjects was 617 cc per minute By hyperventilation it was possible to reduce the cerebral blood flow approximately one half By breathing 10 per cent carbon dioxide, it was possible to double the cerebral blood flow Under the *conditions* of these experiments, the major changes which occur in arteriovenous differences of oxygen are the result of change in the cerebral blood flow However, in all cases the oxygen uptake of the brain was reduced by high carbon dioxide concentrations; no consistent change in oxygen uptake occurred with hyperventilation

Abdominal Rigidity a Symptom of Concussion of Spinal Cord.—Abbott limits the meaning of the term "concussion of the spinal cord" to a transitory syndrome following indirect injury to the spinal cord Seven cases are described in which the syndrome of transitory sensory paralysis of the lower extremities with involvement of the trunk into the thoracic region was accompanied with abdominal rigidity and paralysis in extension of the lower extremities No clinical evidence of gross damage to the spinal cord was found in 5 cases, and in 2 a small quantity of blood was observed in the spinal fluid All the patients recovered The symptoms referable to the lesion may be due to a so-called *molecular* disturbance, and the reversible structural changes within the nerve cells and fibers, associated with probable changes in electrical conductivity and excitation, are not unlike those in cerebral concussion The syndrome resembles that of the decerebrate state, for it is manifest below the level of the spinal injury and is due to involvement of the extrapyramidal pathways without interruption of the vestibulospinal tracts

Metastatic Calcification R M Mulligan —p 177

Histoplasmosis in Infancy.—The evidence obtained from a study of pathologic material by Weed and his associates indicated widespread dissemination of Histoplasma The patient was a girl born in Illinois in April 1945 and dying at the Mayo Clinic in December of that year The finding of the organisms in the blood, marrow and lymph nodes suggests that every organ and *tissue was involved to some degree The condition of the adrenal* glands was especially interesting The yeast forms appeared to be actually invading the cortical cells, some of the latter containing so many parasites that they lost their identifying characteristics and appeared as macrophages To consider either the cortical cells as phagocytes or the yeast forms as invaders is unique, since in no other condition has the former been demonstrated, and in other parts of the body the organisms occurred only in phagocytic cells

Congenital Tularemia.—Lide reports what he considers the first case of congenital tularemia The disease occurred in the mother during the eighth month of pregnancy and was followed by infection and death of the fetus The necrotic granulomas *occurring in various organs of the fetus* were similar to those which are usually found in adults Gram negative coccobacilli consistent morphologically with Pasteurella tularensis were demonstrated in chorionic villi The author cites several cases from the literature of tularemia in pregnant women, but the pregnancy usually went to term and apparently normal infants were delivered

The Influence of Unilateral Exercise on the Contralateral Limb.—Hellebrandt and his associates point out that unilateral exercise of the heavy resistance type is associated with increased strength in the symmetrical muscle groups of the unexercised contralateral limb This phenomenon is referred to in the psychologic literature as "cross education" Fifteen normal healthy adult women were subjected to cross education experiments It was found that unilateral heavy resistance exercise which rapidly augments the strength and staying power of the ipsilateral limb has a strikingly similar concomitant effect on the contralateral unpracticed limb It is suggested that cross education may serve as a useful therapeutic tool in cases in which volitional control is unilaterally defective or in which contralateral muscle groups are rendered temporarily inaccessible through immobilization

Surgical Treatment of Bone Tumors —Coley thinks that benign tumors of bone require surgical treatment not only for the present symptoms but for future malignant potentialities The form of therapy differs with the type, the extent and the location of the tumor, but seldom should amputation be required Surgery is also indicated for malignant tumors of bone This implies amputation in most instances particularly for those types that are radioresistant High thigh amputation for tumors of the lower femur has proved an acceptable substitute for routine hip joint disarticulation For tumors in other situations, amputation proximal to the bone involved is generally advisable, although exceptions exist Under certain conditions and in special locations malignant tumors may be dealt with successfully by conservative surgical measures such as local excision, resection, curetage, scapulectomy and patellectomy rather than by amputation

*Newer Aspects of Virus Hepatitis R B Capps —p 161
Ocular Tuberculosis Three Case Reports L P Brumm —p 168
Premedical Program S Dorst —p 176

Virus Hepatitis —Capps says that large outbreaks of virus hepatitis have generally been restricted to armies in time of war During World War II the disease reappeared in epidemic proportions in most armies Following the administration of yellow fever vaccine to United States troops a large outbreak occurred in 1942 Subsequently the disease was prevalent in certain overseas theaters It has now been clearly demonstrated by transmission of the disease to human volunteers that virus hepatitis is due to a filtrable virus This term is used to include catarrhal jaundice, infectious hepatitis, infective hepatitis and homologous serum jaundice Two immunologically separate strains have apparently been identified, namely the homologous serum and the epidemic types This distinction is supported by differences in the length of the incubation period and in the clinical picture Thus the former is essentially afebrile and usually runs a more protracted course The pathologic lesion consists essentially of an inflammatory reaction in the portal areas and within the lobules and varying degrees of necrosis of the parenchymal cells The author stresses the danger of transmitting the disease through blood, blood products and syringes The most important single form of therapy is bed rest

Complications of Topical Use of Sulfonamides —Dobes describes reactions which follow the topical use of sulfonamides There is a vesicular reaction, with erythematous, vesicular and sometimes bullous lesions The areas of contact are involved but the eruption may become generalized even though application of the drug is discontinued Eczematoid reaction is characterized by weeping plaques, which usually appear in and around the areas of contact Sometimes bleeding and sanguineous crusts are present Occasionally some vesiculation is noted at the periphery of the plaques In severe reactions a sensitizing eruption called an "id" may appear on distant parts of the body Clinically, the "id' eruption is macular, maculopapular and vesicular The nummular eczema like eruption usually appears after prolonged local use of the sulfonamide drugs The eruption is characterized by oval, circumscribed, infiltrated, weeping patches The lesions frequently appear as if studded with droplets of serum There is a dermal, epidermal sensitivity in which the eruptions are varied in appearance and severity and may give a picture of a typical drug eruption The treatment of eruptions due to sulfonamides should always be simple and soothing When a reaction occurs the drug should be discontinued Ultraviolet rays and roentgen rays are contraindicated because sulfonamides are photosensitizing drugs The use of sulfonamide drugs for local application should be discouraged and the free sale over the drug store counter should be prohibited

Tuberculosis of Breast.—Tuberculosis of the breast occurs probably once for every hundred cases of carcinoma Pregnancy and lactation are thought to be predisposing factors It is usually unilateral and rarely exists in association with carcinoma The condition should be considered in the differential diagnosis in the presence of a sinus in the breast, a retracted nipple, a diffuse nodularity with increase of fibrous stroma and with enlarged lymph nodes Drainage from a sinus tract should be studied Since 1938 2 proved cases of tuberculosis of the breast have been observed at the University Hospitals in Iowa City In both of these there existed an underlying pulmonary tuberculosis, and 1 of the women has already died Tuberculosis of the breast is usually primary, develops by direct invasion, and usually involves the regional lymph nodes. The disease does not undergo regression, has no complications and is treated successfully by radical mastectomy.

Effect of Certain Mineral Elements on Production of Penicillin in Shake Flasks. H. Koffler, S. G. Knight and W. C. Frazier.—p. 115.

Cultivation of Bacterium Tularense in Eggs.—Downs and her associates attempted to determine whether Bacterium tularense, when grown in the presence of living cells in embryonated eggs, might be a better antigen than when grown in vitro. They found that Bact. tularense multiplies abundantly in the tissues and fluid of the embryonated chicken or duck egg. Multiplication is greatest in the yolk sac, particularly after yolk sac inoculation. The virulence affects the multiplication of the organism in the embryonated egg and the survival of the embryo. The less virulent strains of Bact. tularense did not multiply as abundantly as the virulent organisms. Serial passage of virulent Bact. tularense through eggs increased the virulence of the organism for chick embryos but not for mice. Storage in the frozen state or in the cold did not modify the virulence of the surviving organisms, but the percentage of organisms surviving after three months was relatively small, amounting to 1 per cent of the original number of organisms present.

Metabolic Studies in Louse Borne Typhus.—Tierney and Yeomans studied patients with typhus admitted to the United States of America Typhus Commission ward during the first two weeks of their disease. The diagnosis of louse borne typhus was confirmed in all of these cases by the Weil-Felix and complement fixation tests. A study of the electrolyte pattern of the serum revealed that early in the disease the chlorides were low in 62 per cent of the cases, but with few exceptions the carbon dioxide content was normal. The p_H was normal in all the patients except 1 who had renal failure and acidosis. The total base was normal in all the cases studied except 1. In all instances the undetermined acid anions were increased, and in the majority of cases they were as great as in severe metabolic acidosis. The total serum proteins were normal in approximately 75 per cent of the patients, but the majority showed a depression of the albumin fraction and a very striking elevation of the globulin fraction. The increase in globulins represented a percentage increase of over 40 in the average case. There was no relationship between nitrogen output and intake or between protein destruction and azotemia. A high protein, high caloric diet decreased nitrogen wastage and loss of body weight during the acute phase of typhus. Positive nitrogen balances were obtained in 5 cases.

Renal Reabsorption of Chloride and Phosphate in Hypertension.—Farnsworth studied the filtration rate, renal blood flow and chloride excretion by means of concomitant clearance tests of insulin, diodrast and chloride in a group of normal subjects and a group of patients with "essential hypertension." Protracted studies were done by the same method on a single individual without vascular or renal disease and a patient of corresponding age and sex with well established hypertension.

Tabulation of chloride clearance and urine flow in these groups showed a fixed range of chloride clearance independent of the urine flow in normal persons. In the hypertensive patients the chloride clearance tended to vary directly with the urine flow. Plotting of U/P (urine/plasma) chloride against U/P insulin in the normal cases resulted in a straight line relationship of constant proportion, which in the group study, as in the individual, dropped below U/P chloride values of 1 and approached zero. It was therefore demonstrated that under conditions of extreme diuresis the tubular epithelium actively retracted the chloride from the filtrate, with the theoretical end result that if no water whatever was reabsorbed in the tubules all chloride would be reabsorbed and the urine would be a chloride free filtrate unmodified with respect to inulin. In order to explore the application of this method of analysis, phosphate values on the same case were similarly calculated and graphed. Phosphate was found to behave like a nonthreshold substance the U/P ratio of which declined with the U/P inulin to a theoretical value of 1. The U/P chloride in both group and individual hypertension studies was higher at all U/P inulin ratios than the normal curve. Such an alteration in behavior toward chloride represents an impairment of the normal reabsorption mechanism.

Influence of Pteroylglutamic Acid on Absorption of Vitamin A in Sprue.—Darby and his associates review observations on 4 patients with sprue who were treated with doses of either 5 or 15 mg. daily of pteroylglutamic acid administered either orally or intramuscularly. None of the patients received supplements of carotene or vitamin A, and there has been no effort to alter their usual diets. It was found that the low serum carotene levels observed in relapse were gradually increased following therapy. The carotene returned to its previous low level during the relapse of 1 patient following withholding of pteroylglutamic acid and again rose after a second period of therapy with pteroylglutamic acid. Following therapy with pteroylglutamic acid an improved ability to absorb vitamin A is indicated by a rise in serum vitamin A following the administration of an oral test dose. The fact that this curve reverted to a typical flat curve during a relapse after the withdrawal of treatment is further evidence of the influence of this factor on the absorption of fat soluble substances. It is suggested that the M group of vitamins, of which pteroylglutamic acid is a member, plays an important role in the normal physiology of the gastrointestinal tract.

Treatment of Hemophilus Influenzae Meningitis.—Alexander states that streptomycin is the most effective single antibacterial agent against Hemophilus influenzae. Since it is bactericidal, its action is rapid and effective against large bacterial populations, both in vivo and in vitro. Streptomycin, like all other single therapeutic agents, is limited if the infection is of sufficient severity; resistance of the organisms is the chief cause of failures. Experimental evidence and response in 1 patient suggest that this defect may be overcome if sulfadiazine is used in conjunction; the two agents have different modes of action, and therefore organisms resistant to one can be expected to be sensitive to the other. Whether in some patients specific antiserum is needed cannot be answered from the limited experience. There is suggestive evidence that the incidence of residual cerebral damage is less when all three therapeutic agents are used together initially rather than in sequence after a trial of each separately.

Subdiaphragmatic Splanchnicectomy for Arterial Hypertension.—Peet states that the least extensive splanchnicectomy is the subdiaphragmatic type of Adson and Craig. The bilateral supradiaphragmatic splanchnicectomy that Peet has been carrying out for the past thirteen years is much more extensive. Somewhat more complete is the denervation practiced by Smithwick, which combines the two mentioned operations. A much more extensive denervation is produced by the nearly total sympathectomy of Grimson. At Peet's clinic bilateral subdiaphragmatic splanchnicectomy has been done on more than 1,500 patients. He does not think that additional denervation is necessary. The majority of the patients have been followed for from one to twelve years since the operation. Symptomatic relief has been striking. Excruciating headaches, usually suboccipital, nervousness and irritability, insomnia and distressing palpitation have been greatly relieved or completely eradicated in 86 per cent of the patients still living. This percentage of improvement has persisted almost unchanged over postoperative periods of five to twelve years. Such symptomatic relief is not necessarily dependent on a significant lowering of the blood pressure or improvement in cardiac or renal function. The blood pressure, both systolic and diastolic, was significantly reduced five to twelve years after splanchnicectomy in 81.3 per cent of the patients still living. The funduscopic findings in cases that before operation showed angiospastic retinitis with or without hemorrhages or exudates now show absence of angiospasm, hemorrhages or exudates in 82 per cent. The cardiac status showed a similar improvement. The renal function following splanchnicectomy has shown definite improvement both in water concentrating ability and in urea clearance. Relief of incapacitation and probable prolongation of life are reported The relief afforded by bilateral splanchnicectomy is demonstrated on the basis of 3 typical case reports.

Penicillin for Gonorrhea in Women.—Perkins and Brewster report data collected from twelve clinics that cooperate with the Division of Venereal Diseases, Massachusetts Department of Public Health The study includes information on gonorrhea in women who had been treated with varying courses of intramuscular injections of an aqueous solution of penicillin Two hundred and thirty-four courses of treatment were given in 200 cases The best results were obtained by the use of 150,000 units or more of penicillin divided into three equal doses spaced two hours apart.

Experimental Appendical Peritonitis.—Kay and Lockwood produced experimental peritonitis in 128 dogs by ligation of the base of the appendix. The significance, in respect to survival, of the balance of fibrinolytic and antifibrinolytic factors in the blood of 37 of these dogs has been investigated. There was evidence of spontaneous lysis of plasma fibrinogen, and fibrin occurred with much greater frequency in animals which died than in 16 animals which survived. Lysis invariably occurred in samples drawn within twelve hours preceding death Sharp fluctuations in available fibrinogen nitrogen were observed during the course of the disease in all the animals The correlation between fibrinogen nitrogen levels and the activity of fibrinolytic factors is not clearly established. Animals which survive show levels of fibrinogen nitrogen approximately 65 per cent greater than preoperative values The fibrinolytic activity of chloroform treated serum was significantly higher in dogs which died than it was in dogs which survived. The preoperative administration of trypsin in amounts sufficient to build up the antiproteolytic activity of the serum had a significant influence on survival Only 1 of 15 animals so treated died, which contrasts with a mortality rate of 41 7 per cent in the 91 control animals Neither penicillin nor heparin was of therapeutic value in experiments on small groups of dogs

Streptomycin in Surgical Patients.—According to Zintel and his associates, streptomycin has exerted a beneficial influence on the course of experimental peritonitis in 5 dogs, as compared with 5 control animals which did not receive special medication, but its therapeutic effect was not as great as that observed in 5 dogs which were given a combination of sulfonamides and penicillin Streptomycin administered in doses of 1 0 Gm per day to 15 patients for periods of from six to ten days appeared to be a very effective agent in reducing the bacterial count in stools It reduced the coliform organisms to a greater degree than succinylsulfathiazole and reduced Streptococcus fecalis and Clostridia to a much greater extent

17-Ketosteroids and Adrenal Tumors.—Johnson and Nesbit report 3 proved cases of adrenal cortical carcinoma in a woman aged 31, in a girl aged 2 and in a man aged 43, associated with elevated total 17-ketosteroid excretion in which fractionation into alpha and beta portions has been of definite value in the differential diagnosis. It is concluded that the determination of the urinary 17-ketosteroid excretion is of differential diagnostic value in masculinizing syndromes and that an elevated total 17-ketosteroid excretion with an abnormal increase in the beta fraction is strongly suggestive of adrenal cortical carcinoma.

Simultaneous Bilateral Stimulation of Body in Lesion of Parietal Lobe P. W. Nathan.—p. 325.

Traumatic Amnesia.—According to Russell and Nathan it is now generally agreed that the disorders of consciousness following head injury are usually dependent on neuronal trauma and are rarely due to vascular complications. Many head injuries are accompanied with instantaneous paralysis of brain function. During the period of brain paralysis there can be no registration of surrounding incidents and accordingly there is amnesia for events occurring during this time. The function of memory is usually regained at about the same time at which the last trace of confusion disappears, and the period of post-traumatic amnesia is then at an end. Retrograde amnesia is for events which occurred before the injury while the patient was still fully conscious. The events occurring during this period were often dramatic, yet the injury intervenes and these events are thereby prevented from being retained, or if they are retained they cannot be recalled. The retrograde amnesia is in most cases for only a few moments. The motorist remembers approaching the crossroads, the cyclist remembers losing control on a steep hill or the window cleaner remembers losing his balance. Distant memories return first and loss of memories for the previous few years may be so complete for a time that the patient believes himself to be several years younger. The recovery of this type of memory loss is by shrinkage toward the present time. The long amnestic period recovers not so much according to the relative importance of events forgotten as according to the time before the injury that the events occurred. There is thus a vulnerability of memories which depends directly on their nearness to the injury. A long retrograde amnesia is almost always associated with a long post-traumatic amnesia. A long retrograde amnesia, whether temporary or permanent, occurs after severe neuronal commotion, and severe neuronal commotion has a much more damaging effect on erasing recent than remote memories.

Multiple Cutaneous Horns in a Young Girl.—Walker reports that at the age of 2 years a girl who came of a poor white nomadic farming family in Southwest Africa had an eruption on the lesions of which horns began to grow. Each horn persisted for about eight months, grew 1 to 5 inches in length, and then fell off. Successive crops of these horns have appeared on the skin for the last fifteen years and she has never been free from them. One of the hyperkeratotic patches on the leg was treated with contact x-rays; the result was some scarring and no tendency to recurrence at that site. On the theory of psoriasis, solution of potassium arsenite was given by mouth. The application of Adamson's tar ointment to the body lesions and an ointment containing oil of cade 12 per cent with ammoniated mercury to the palms and soles prevented the growth of horns and hyperkeratotic patches for the five months during which she stayed in hospital.

Plague Meningitis.—Koenigsfeld and Nambiar report 2 cases of plague meningitis which they observed among 41 instances of plague. Diagnosis of plague meningitis was confirmed in a woman aged 47 by the detection of Pasteurella pestis in a culture of the lumbar puncture fluid obtained on the day before death. Lumbar puncture was not performed on a girl aged 7, and the diagnosis was made on clinical grounds. The symptoms were due to a meningitis. Head retraction and opisthotonos indicated severe meningeal irritation, which, in the opinion of the authors, could be explained only by an acute breakdown of the blood-cerebrospinal fluid barrier, if not for the Pasteurella itself, so at least for the toxins. In both cases the meningeal signs occurred after some initial improvement. Both patients seemed to respond favorably to sulfonamides and succumbed at a comparatively late stage of the disease. Sulfadiazine probably lessened the virulence of the germ without rendering it entirely harmless, with the effect that the disease took a more chronic course and meningitis had time to develop. If this conclusion is correct, more cases of plague meningitis may be observed in the near future, as sulfonamides are now in general use in the treatment of plague.

*Surgical Treatment of Sjögren's Syndrome (Dry Eye and Mouth): Results at End of Twenty-Eight Months of Double Section of Vertebral Nerve; Nature of Disease. R. Leriche.—p. 77.
Physiopathology of Hormonal Osteoporoses. A. Lichtwitz.—p. 78.
Extrapleural Detachment of Pulmonary Adhesions Under Control of Pleuroscope: (Michetti's Operation). I. Braillou.—p. 80.

Surgical Treatment of Sjögren's Syndrome.—A woman aged 50 had been troubled with dry mouth for a decade. Her eyes were dry and she had small areas of telangiectasia in her face. She was in the habit of carrying a small flask of water to moisten her mouth occasionally and also an eye wash to moisten her eyes. Examination was essentially negative. Leriche suspected an atypical scleroderma. He decided to try sympathetic infiltration, hoping that the resulting hyperemia would reactivate the lacrimal and salivary glands. This woman apparently had Sjögren's syndrome, but the author did not identify it as such at the time, not having learned about this condition until later. In the course of several days, various procaine infiltrations (stellate-pericarotid) were made and since they induced the desired changes, sympathectomy was decided on. First the roots of the vertebral nerve were cut and a substellate segment of the cervical chain comprising the intermediate ganglion was removed. The resulting improvement on the right side induced the author to perform sympathectomy also on the left side. The disagreeable dryness of eyes and mouth disappeared. The improvement persisted for about two years, when the woman died as the result of a hemorrhagic purpura. The author suggests that, although the results were good, it might possibly be better to attack the middle part of the cervical chain.

*Roentgen Therapy in Plastic Induration of Penis (Peyronie's Disease). R. Sanchez Cordero.—p. 495.

Roentgen Therapy in Plastic Induration of Penis.—Five out of 7 patients between the ages of 35 and 60 with plastic induration of the penis were given roentgen applications in doses which varied from 250 to 400 roentgens every two weeks up to a total dose of from 1,500 to 2,500 roentgens. The other 2 patients were treated by radium with a total dose of 1,000 radium units. The results for the entire group were as follows: Three patients were cured, eight to eighteen months after completion of treatment; 2 were improved, which improvement persists up to now, less than one year after completion of treatment; 1 patient was improved only slightly, and 1 patient failed to report.

Hypoproteinemia.—Bing studied the problem of hypoproteinemia in 500 patients with medical disorders, whom he examined by means of a rapid glass bead test. The limit of 6 per cent was chosen as the lowest normal value. Hypoproteinemia was detected in 66, or 13 per cent, of the 500 patients. It was somewhat more frequent in males than in females; in most instances it was moderate; only 10 had values lower than 5 per cent. Hypoproteinemia occurs in three forms: (1) as isolated hypoalbuminemia in diseases of the liver and kidneys and in most cases of gastrointestinal cancer; (2) as isolated hypoglobulinemia, which is rare and was observed in 1 patient with chronic lymphatic leukemia; (3) as the simultaneous reduction of the two fractions, which is most frequent and is found in a number of different diseases. The cause of hypoproteinemia may be hydremia, reduced supply, faulty resorption, defective synthesis or a combination of two or more of these causes. There are also cases in which the cause is uncertain.

Mucin Content of Gastric Juice.—Brummer presents a new method of determining mucin, which he employed in tests on 145 persons, 50 of whom were healthy and 95 of whom had various gastric disorders. The mucin content of the gastric juice varied from 0.15 per cent to 1.5 per cent, the average being about 0.5 per cent. After a test meal the mucin content was slightly higher than with an empty stomach. Histamine and insulin, on the other hand, appeared to have no effect on the mucin content. No clear difference was found between the mucin content of persons suffering from gastric disorders of different kinds. It is particularly to be noted that the mucin content of the gastric juice of peptic ulcer and gastritis patients was normal.

Examination of Duodenal Juice in Diagnosis of Celiac Disease. O. Somersalo.—p. 2779.

Hepatosplenomegaly in Adults.—Rasmussen discusses 76 cases of the syndrome, representative of all parts of the country, treated during three years at the Rikshospital. The occurrence of anemia, most often isochromatic, often hyperchromatic, and of leukopenia and thrombopenia, is common to many of the cases. Although the liver is diseased in nearly all the cases, the different tests of liver dysfunction give positive results chiefly in the cases of primary hepatic disease. A case of each of the following is described: (1) juvenile liver cirrhosis with gradual disappearance of most symptoms, (2) liver cirrhosis of Laënnec type with generalized angiofibromatosis, resembling idiopathic sarcoma of Kaposi, (3) lymphoid infiltration of a number of parenchymatous organs, terminating in reticulosarcoma, (4) nonleukemic myeloid hepatosplenomegaly and (5) chronic acetanilid intoxication with hepatosplenomegaly.

Prognosis in Acute Nephritis.—Of 175 patients with acute nephritis treated from 1934 to 1944, 120 were under 25 years of age, 80 of these under 16, and only 11 were between 50 and 75. Ten died during hospitalization, 4 after discharge. Of the 148 followed up 108 are well, 29 are not cured and recurrence nephritis appeared in 11. Ramberg finds that the mortality during the acute phase of the disease is low. The percentage of recovery is highest in the younger age groups. The prognosis is relatively good in patients with hypertension encephalopathy, more unfavorable in cases with grave proteinuria and considerable edema. The acute initial stage was characteristic in patients whom reexamination showed to be well, while in the majority of those not cured the nephritis had begun insidiously without acute infectious disease. As in the so-called focal nephritis and the acute exacerbation in chronic nephritis, the incubation time between the introductory infectious disease and the changes in the urine is remarkably short in recurrence nephritis, generally about twenty-four hours, as against from six to sixteen days in regular acute nephritis.

Book Notices

The Principles and Practice of Tropical Medicine. By L. Everard Napier. Cloth. Price, $11. Pp. 917, with 199 illustrations. Macmillan Company, 60 5th Ave., New York 11, 1946.

This textbook is an unusually complete and useful work covering the important tropical diseases. Its value is greatly enhanced by the inclusion of a well selected bibliography at the end of each chapter. The author, for many years director and professor of tropical medicine of the Calcutta School of Tropical Medicine, has drawn extensively on his own wide clinical and research experience and that of his colleagues. Certain aspects of the presentation therefore are naturally reflections of the Indian scene. These, however, enhance the interest and value of the volume. This is particularly true of the discussions of cholera, kala azar, malaria, plague and the still unsolved problem of the identities of the "tick typhus" fevers of India.

The first fifty-one pages are devoted to the general problems of health presented by tropical residence and include the elements of climatology, hygiene and adaptation. Thereafter the succeeding chapters are a series of standard presentations of individual diseases or related diseases, in each instance preceded by an index giving pagination. The geographic distribution, epidemiology, etiology, pathology, clinical phenomena, treatment and control measures are discussed in adequate detail. Much of historical interest is incorporated in the text, and some of the epidemologic features and problems are presented in an unusually interesting fashion.

The discussions of treatment are detailed and complete. Much of the new information acquired during the war years is presented critically, for example the usefulness and not less definite limitations of the aromatic diamidines in the treatment of kala azar. While some American clinicians might not agree with certain of the plans for therapy, the author has the great advantage of an unusually broad and comprehensive experience in the practice of tropical medicine in India on which to base his conclusions.

The volume is well organized and well illustrated with drawings, photographs, charts and tables. It is more than usually readable. Descriptions of parasites and life cycles are complete but not emphasized to the point of disturbing the balance of the text as a whole. The subject and author indexes occupying the final forty-eight pages amply provide for ready reference. This volume is particularly suitable as a textbook for graduate students in tropical medicine and is invaluable to the physician and medical teacher with serious interest in this field. It is an extremely important addition to the authoritative textbooks on tropical medicine and cannot be too highly recommended.

Postgraduate Obstetrics. By William F. Mengert, M.D., Professor and Chairman, Department of Obstetrics and Gynecology, Southwestern Medical College, Dallas, Texas. Drawings by Ruth Maxwell Sanders. Cloth. Price, $5. Pp. 392, with 123 illustrations. Paul B. Hoeber, Inc., 49 E. 33d St., New York 16, 1947.

The author in his preface states that the book is written for the physician who is doing general practice and who will deliver some 1,800 women during a lifetime. The material in the book is prorated according to the incidence of the various complications and diseases encountered by such a physician. The physician who performs at the most a hundred forceps and thirty cesarean sections during a lifetime has no business performing any of these operations. The author would have done well to omit the chapter on obstetric forceps, on cesarean section and on craniotomy and vaginal hysterotomy, using the space thus saved for enlargement on breech and version. Postpartum sterilization by the general practitioner should have been omitted. The chapter on sterility and many of the procedures listed under "Laboratory" should have also been omitted as well as the nursing technic, which comprises some ten pages. The author states that at least half of all patients with hyperemesis do not vomit after admission to the hospital. Obviously these patients are not suffering from hyperemesis gravidarum. The author has failed in his attempt to write a book for the general practitioner, who will be served better by one of the standard textbooks on obstetrics.

Essentials of Clinical Proctology. By Manuel G. Spiesman, B.S., M.D., Proctologist, Mt. Sinai and Edgewater Hospitals, Chicago. Foreword by Anthony Bassler, M.D., F.A.C.P., LL.D. Cloth. Price, $4. Pp. 238, with 62 illustrations. Grune & Stratton, Inc., 443 4th Ave., New York 16, 1946.

This volume, which is an outgrowth of lectures on diseases of the anus, rectum and colon given to medical and postgraduate students, apparently is intended to be a handbook, but the brevity with which some of the subjects are treated makes use of the book for this purpose scarcely feasible from a practical point of view. The chapter entitled "Proctitis, Sigmoiditis, Colitis" is especially brief and is little more than a short abstract of the subject.

In his preface the author states that "the following new material and advances in proctology have been incorporated in this book: the use of the sulfa drugs in postoperative bleeding and ulcerative colitis; anesthetic oil in the treatment of pruritus ani, fissure in ano and intractable anal pain; the diagnosis and injection treatment of coccygodynia . . .; combined pentothal and novocain anesthesia in anorectal operations; injection treatment of hemorrhoids and prolapse; lymphopathia venereum, rectal stricture and prestricture (fourth venereal disease); the treatment of anorectal surgical complications; pectenosis and pectenotomy . . .; a clinical application of anorectal anatomy; making anorectal operations less painful; a new anatomical conception of the external sphincter muscle and its surgical management in fistulas; the 'critical angle' and its relationship to anorectal incontinence; a successful operation for pilonidal cyst; a résumé of causes and treatment of constipation and advanced treatment of venereal diseases of the anorectum." A careful study of the subject material of the book fails to reveal any reason for this statement. The medical student and busy general practitioner, however, doubtless would find something of interest in the book if the limitations stated in the preface are kept in mind.

Teen Days: A Book for Boys and Girls. By Frances Bruce Strain. Cloth. Price, $2.75. Pp. 183, with illustrations. D. Appleton-Century Co., Inc., 35 W. 32d St., New York 1, 1946.

This small volume is intended not only for teen agers but for parents and teachers as well. The primary purpose of the author is to allay the fears and uncertainties of this period of life through a more profound appreciation and understanding of adolescence as a transitional stage involving rapid growth and development. The physical, biologic and emotional changes which are apt to be puzzling and disturbing both to the children and to their parents are discussed, with emphasis on individual differences. The book presents a fairly complete picture of the problems of adolescence and at the same time avoids a too detailed discussion of specific subjects. The discriminating choice of material and informal manner of presentation indicate the author's intimate knowledge of teen agers and the questions they are most likely to ask about themselves and their relationships with others.

Detracting from the value of the book are many ill advised and erroneous statements related to medicine, which, on the surface, may be acceptable to the layman yet from the physician's point of view are unscientific. The author's advice to the boy who finds he is going to be a "shorty" is "The first thing to think of is the pituitary gland. In the hands of experienced physicians an extract called pituitrin may give an extra lift to the growth-making forces." The girl suffering from anemia is told to eat "red meats, egg yolk and rich blackstrap molasses." Menstrual cramps "may also be caused by lack of exercise causing tight muscles and they may be caused by poor posture when the ligaments running between the back and the legs tilt the pelvis improperly. Stretching exercises . . . relieve the nerve pressure which causes the pain." For further information the reader is referred to a pamphlet published by the Billig Clinic, Los Angeles. Nutritionists would probably object violently to such statements as "chocolate malted milk is tops for food value and vitamin content. It carries about twice as much as the same amount of whole milk."

It is obvious that a thorough editing of the portion of the book dealing with matters of a medical nature is essential in order to render it suitable for popular consumption.

Ophthalmia Neonatorum: The Problem After Thirty Years of Statutory Notification and Sixty Years of Credé Prophylaxis. By Arnold Sorsby, M.D., F.R.C.S., Research Professor in Ophthalmology, Royal College of Surgeons of England and Royal Eye Hospital, London. With a foreword by Sir Allen Daley, M.D., F.R.C.P., Medical Officer of Health, County of London. Institute of Ophthalmology Monographs No. 1. Paper. Pp. 66, with 11 illustrations. Paul B. Hoeber, Inc., New York 16; London: Hamish Hamilton, Ltd., 1945.

This monograph presents a statistical study of the incidence of ophthalmia neonatorum and subsequent blindness. Sorsby quotes figures of other authors for incidence. From 1934 to 1943 there was visual impairment in 3.4 and blindness in 0.8 per hundred thousand births in England and 2.8 and 0.4 respectively in Scotland. From 1938 to 1942 there was 1 per thousand cases of gonococcic infections with use of silver nitrate and 0.7 with use of other silver salts as prophylaxis. The author presents data on the use of sulfonamide drugs and penicillin in the treatment of disease. He concludes that there is no smaller incidence of ophthalmia neonatorum today than there was twenty-five or even forty years ago, though its incidence as a result of gonococcic invasion is smaller because the silver nitrate does not destroy the other organisms or virus. The incidence of blindness is less. This he attributes to the success with the sulfonamide drugs and penicillin. He believes that the real solution to prophylaxis is the intensive study and treatment of the mother's birth canal before labor. Nothing new has been contributed. The pamphlet is valuable for its statistics and tables.

Pattee's Dietetics. By Alida Frances Pattee. Twenty-Third edition revised by Hazel E. Munsell, Ph.D., and others. Cloth. Price, $3.50. Pp. 736, with illustrations. G. P. Putnam's Sons, 2-6 W. 45th St., New York 19, 1945.

Having reached its twenty-third edition, Pattee's Dietetics has proved its usefulness. The entire book has been either revised or rewritten by Dr. Hazel E. Munsell and by authorities in nutrition, medicine and nursing. The text is well organized and is simply and concisely worded. Because of the experience and training of those who prepared it, it is authoritative. It can serve both as a textbook and as a work of reference and will continue to have wide appeal to all those who deal with the feeding of both well and sick persons regardless of whether they are professionally trained or not. The clearness of the text, which at the same time gives considerable detail, makes this possible. It discusses both the fundamentals of nutrition and its practical application.

To the physician this book commends itself especially as one that he can recommend to intelligent patients or to the families of patients when he wishes to give specialized nutrition instruction. It gives methods as well as the scientific background. In the hands of an intelligent patient the book can save the busy practitioner much time. As a textbook and reference work for student and graduate nurses alike it is extremely useful. It also finds an important place in colleges of home economics and other schools where courses in foods, nutrition and dietetics are being taught.

The book is well illustrated and of convenient size. Its printing is easily read. At the end of each section there are also provocative questions for the student. The appendix contains 76 pages of useful reference material, some of which is difficult to find elsewhere. An unfortunate typographical error was made in table I of the appendix, where mcgm. should read mg. in the ascorbic acid column. In the next edition greater emphasis might well be placed on the importance of optimum nutrition in pregnancy and lactation.

Ambulatory Proctology. By Alfred J. Cantor, M.D., Associate Proctologist, Kew Gardens General Hospital, Long Island, New York. With a foreword by Beaumont S. Cornell, M.D. Cloth. Price, $8. Pp. 524, with 281 illustrations. Paul B. Hoeber, Inc., 49 E. 33d St., New York 16, 1946.

The title of this volume suggests that the author is dealing only with ambulatory proctology. A study of contents of the book, however, reveals practically no difference from the standard type of book which has been written on the subject of diseases of the terminal portion of the colon, rectum and anus. The work has value and shows that the author has devoted a considerable amount of time and study to its preparation. One, however, cannot refrain from regretting that the author included a sketch which depicts the application of an elastic ligature around prolapsed rectal tissue and devoted a portion of the text to a description of so crude a method of treatment. If it is included because it is an ambulatory procedure, it is difficult to conceive that a patient can go around in an ambulatory fashion with part of his rectum protruding and a constricting band of elastic material tied around it so tightly that finally the protruding tissue sloughs off. The author explains his conception of ambulatory proctology in the words "If a proctologist excises a pilonidal cyst, performs an extensive hemorrhoidectomy or amputation of a rectal prolapse and then returns the patient to his home, although not necessarily to bed, that case has been treated by ambulatory proctology." It is evident that the author wishes to call the attention of proctologists to the fact that much treatment can be administered without confining a patient to a hospital. The bibliography is extensive. The author has prepared a book which contains some valuable information on the subject of proctology.

Tutoring as Therapy. By Grace Arthur, Ph.D. Cloth. Price, $1.50. Pp. 125. Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

This small book is rich with the overtones of the author's own vast experience. Parents and educators and others interested in children will like the fine simplicity, brilliant individual design and precision of the author. The rule of the psychologist in diagnosing the difficulty, suggesting the teaching method and checking the progress of the work is clearly shown. The volume is divided into six chapters, on (1) an early experiment, (2) adventures in tutoring, (3) selection, training and supervision of tutors, (4) methods used in remedial teaching, (5) tutoring as therapy and (6) tutoring as a community project.

The closing paragraph of the book states that, "in order for tutoring as a community project to operate successfully, it is necessary for schools, agencies, parents, children, physicians, tutors and supervising psychologist to work together to enable each child to get the kind and amount of teaching he needs to help him take his place as a self-respecting member of the group. The cost of a tutoring program is insignificant as compared with the cost of dealing with delinquent behavior that results when school maladjustment and failure to learn are ignored." This book is geared for a wide and enthusiastic response.

Textbook of Abnormal Psychology. By Carney Landis, Professor of Psychology, Columbia University, New York, and M. Marjorie Bolles. Cloth. Price, $4.50. Pp. 576, with 49 illustrations. Macmillan Co., 60 Fifth Ave., New York 11, 1946.

Within this volume is a great deal of information probably not suited for its intended readers, the undergraduate students. Its failure derives from an attempt to be psychologic and psychiatric and the authors' desire to be medical and assume a broad point of view which they cannot achieve. For the student confusion rather than interest may result from methodically studying the book, although certain chapters may well be used for introductory orientation. Other contemporary works with the same title are superior.

A B C of Medical Treatment. By E. Noble Chamberlain, M.D., M.Sc., F.R.C.P. Oxford Medical Publications. Fabrikoid. Price, $3. Pp. 206. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1946.

This "pocket size" book is divided into several parts: the major part, comprising 142 small pages, is devoted to sketches of the therapy of about 235 diseases of main symptoms; the second largest section comprises 57 pages on diets; then there follows 1 page on dosage for children, 2 pages on penicillin and not quite 4 pages of index. The author states that his purpose in writing the book has been "to provide a brief account of the treatment of the more common medical ailments," and there is ample evidence that both he and his collaborator, a dietitian, have not slighted their task. This is not a book put together in slipshod fashion; indeed, the conciseness of many of the thumbnail sketches it contains is admirable. But one is at a loss to understand what is gained by such an achievement. Surely in our time, when therapeutics is mounting to a place among the more exact and exacting disciplines in medicine, no worthy doctor will be satisfied with the bare, picked skeletons of treatments. Should one be willing to write for the few who will accept the little that this book provides?

SEVERE PROLONGED DIARRHEA

To the Editor:—A white woman aged 39 began to have severe diarrhea six weeks ago, twenty to thirty movements a day, accompanied with rectal tenesmus and abdominal colic not persistent at one site; the temperature was never over 99.8 F. Two stool examinations were negative for parasites, ova or flagellates, and cultures (including blood cultures) were negative for typhoid, paratyphoid fever and bacillary dysentery. The stool specimens were "practically pure pus,,about 90 per cent polymorphonuclear with a few red cells." Bismuth, kaolin and pectin were ineffectual, but sulfathalidine was satisfactory, and the diarrhea ceased two weeks after the onset. However, the abdominal colic still persists and has become localized in the right iliac region. (Stools have become formed, tenesmus has disappeared.) The colic occurs almost regularly, every three or four days, and seems as severe as biliary or renal colic and is not relieved until an opiate is given. There is rarely emesis with the colic, though there have been three or four attacks of projectile emesis, without colic. Wassermann reaction and urine tests are normal. Sigmoidoscopy was negative. A barium enema was negative except for moderate narrowing of the descending colon, although haustrations were well defined and even increased over haustrations of the ascending and transverse colon. Barium was given orally and there were no findings indicative of regional ileitis. The cecum was abnormally low. A hysterectomy had been performed in 1942 because of uterine fibroids, and a pelvic examination is negative now. (The appendix was removed at the time of the hysterectomy.) Cholecystectomy was performed in 1943 because of stones. There were no complications or sequelae. Would you give an opinion as to the cause of this recurrent severe pain in the right lower quadrant? There is no pain over the kidneys, although sometimes the pain radiates to the vulva. Despite normal urine, is a cystoscopy indicated? In spite of the findings, is this history compatible with a diagnosis of ulcerative colitis?

M.D., New York.

ANSWER.—The severe diarrhea six weeks previous probably was on a pyogenic bacterial basis, since studies for parasites and cultures for the Salmonella group of organisms were negative and the frequency of the bowel movements, the purulent character of the feces and the response to sulfathalidine conform to this impression. While the residual colicky attacks raise the question of a diagnosis of ulcerative colitis, there is insufficient evidence to warrant it. The negative sigmoidoscopy, the absence of gross bleeding at any time, the consistent appearance of normal stools since the diarrhea ceased and the x-ray findings after a barium enema almost rule out this disease. A segmental type of ulcerative colitis is a rare possibility but an unlikely one.

The history does not state whether the patient has any current fever, chills, leukocytosis or other evidence of residual infection. Presumably there are none. However, in view of the severity and purulent character of the preceding diarrhea, one wonders about a lingering infectious process. Perforation and subsequent walling off in the right lower quadrant with an irritating focus could occur after such an initial infection. There is no information concerning the findings. In the presence of an abscess one would expect to find some tenderness, rigidity and a palpable mass. In spite of the disappearance of diarrhea it would be well to check the leukocyte count, repeat the stool cultures, continue search for amebic organisms and repeat the sigmoidoscopy. Amebic infection notoriously lingers in the cecum.

The colic which persisted in the right lower quadrant, it is noted, has differed from the diarrheal colic in that it has been intermittent and localized. Also it required an opiate (dose unstated) for relief. It is not clear whether the earlier colic was so intense. The residual colic with three or four independent attacks of projectile emesis and the rare emesis with colic strongly suggest obstruction of some type. Previous appendectomy rules out consideration of the appendix. The duration of the symptoms excludes a continuous obstruction within the intestine, but an intermittent or partial one remains a possibility. The story lacks any features of the typical sequence of events in bowel obstruction as symptoms of fulness followed by nausea, then vomiting, obstipation, dehydration and fever. As there is no description of physical findings, it is assumed that visible peristalsis, changes in auscultatory findings and distention with tympany were not evident. These considerations and the results of studies after the ingestion of oral barium point against bowel obstruction, ileitis or neoplasm of the small bowel. In view of the history of surgical operations in 1942 and 1943, intermittent mechanical obstruction of some sort remains a possibility.

Since neither jaundice nor acholic stools were described and in view of the cholecystectomy in 1943 and the low location of the pain, biliary tract colic is safely excluded. The location of the pain is atypical too for pancreatitis and pancreatic calculi, and back pain is not mentioned. Calculi evidently were not noted in the course of the x-ray studies.

An ovarian cyst twisted on its pedicle at intervals or inflammation in the right adnexa causing periureteral irritation and spasm seems unlikely in view of the negative pelvic findings.

An intermittent ureteral obstruction due to stone, kinking, spasm, intraluminal growth or extrinsic pressure is suggested by the severity, location and radiation of the pain. The episodes of sudden emesis are common in this condition. The absence of urinary complaints or pain over the kidneys and negative urinalysis do not exclude this diagnosis. It is presumed that the urinalysis included microscopic search for erythrocytes. Were urinalyses repeated soon after attacks of colic? As ureteral colic fits this description, the urinary tract should be investigated. The work-up should include repeat urinalyses after colic, a flat plate and intravenous pyelograms. Cystoscopy and retrograde pyelography may be helpful. If the symptoms persist, laparotomy may be indicated.

FUNGOUS INFECTION OF THE EAR

To the Editor:—A woman aged 45 who lives on a farm has had a persistent fungous infection of the external auditory canal for several years. The fungus is black, and at times a whole colony can be seen as if on a culture plate. Since August 1946 there has been the complication of a chronic draining otitis media. Is there danger of the fungus growing in the middle ear? Mercresin, tyrothricin and 3 per cent gentian violet have been used.

M.D., Ohio.

ANSWER.—It is possible for a fungus to grow in the middle ear. In fact, the fungous growth starting inside the auditory canal may be responsible for the perforation of the drum membrane in the first instance, and for the invasion of the middle ear, according to Gill. However, this is infrequent. Molds may be mixed with pyogenic organisms in chronically infected ears, but the pyogens tend to crowd out the molds.

If the medicaments mentioned in the inquiry have failed, metacresyl acetate with small amounts (1 per cent) of thymol added might be tried. This is introduced on a cotton pledget or gauze wick after careful cleansing of the canal and left in situ for twenty-four hours.

Gill recommends insufflation of boric acid powder containing iodine, thymol and tricresol (1 per cent each) for patients who cannot come for daily treatment. Reeh suggests that such powders have some value "in resistant cases or in chronic otitis media where an associated fungous infection is known or suspected to exist."

Of late, much has been claimed for mixtures of the fatty acids and their salts in liquid powder or ointment form. One example is sodium or calcium propionate-propionic acid mixture.

PENICILLIN DURING LABOR

To the Editor:—Are there any published statistical studies of the use of penicillin during labor? I have used penicillin three times during labor and in each case there was intrapartum or postpartum death of the fetus. Two were cases of inadequately treated syphilis and in the third case there was temperature elevation of 103 F. twelve hours before the onset of labor, the membranes having ruptured spontaneously several days before. Temperature was normal during labor. It seemed possible that the penicilin may have had a deleterious effect on the fetus.

M.D., Ohio.

ANSWER.—It is well known that penicillin passes through the placenta to the fetus, and it will pass to the fetus as early as the tenth week of gestation. There is no evidence that penicillin is harmful to the fetus; in fact, infants born of syphilitic mothers have been found to be normal, so that the agent is an excellent one for use in the prevention of congenital syphilis.

XEROSTOMIA

To the Editor:—A woman aged 47, mother of four children, began to complain of severe dryness of her mouth and lips fifteen years ago, five years after the birth of the last son. Until the present time she has not been able to obtain relief from a variety of treatments, including *estrogenic hormones and stimulation of the salivary glands.* A few weeks ago she consulted a physician in Canada, who recommended *study of* her mouth including her teeth with the idea that the different metals used for fillings might be the cause of this disturbance. Physically the patient does not demonstrate any pathologic lesions in the mouth, nose, throat or elsewhere. Her basal metabolic rate has been slightly below *normal at different times.* Please recommend a course of investigation for this patient and references.

M.D., Michigan.

Answer.—Analysis of the patient described in the query must be based on the assurance of negative local and general organic findings. Xerostomia, or oligosialia, may be noticed only during eating or there may be a constant dryness. Occasionally it may occur with a dryness of the nasal and conjunctival membranes. Specific causes include fever, local oral infection, belladonna and opiate drugs, diabetes mellitus and insipidus, chronic nephritis, local x-ray treatment and "nervous temperament" in the absence of other known cause.

The reflex secretion of saliva involves both the sympathetic and the parasympathetic division of the autonomic nervous system. These can both be affected through higher nerve centers and by drugs. A possible obscure method of producing dry mouth and thirst could be a decrease of the antidiuretic principle secreted by the posterior hypophysis, causing a general diuresis, dehydration and decreased salivation. An adrenergic syndrome is known to affect the nasal circulation in rare cases.

Questions which should be answered include: Is the mouth actually dry? Is there burning or paresthesia? Are the water intake and output and the salt intake normal? Is there glycosuria? Is there any evidence of autonomic imbalance in the heart action, gastrointestinal function or sweating? Has the patient had a neurosis, such as might come from a phobia, or marital and family difficulties? Has any medication been used for years, such as one for constipation, containing belladonna? Does she regularly use an astringent (zinc chloride) mouth wash?

However, in the case described in the query, because of the absence of any pathologic changes, the lack of results from treatment, the age, sex and long duration without other changes, it would seem most probable that the cause is functional or psychosomatic.

Treatment must depend on the results of the analysis. Such simple measures as stopping a pill or a gargle, or the use of a glycerin mouth wash, might be sufficient. The use of nicotinamide injections over long periods could be used if the tongue is not normal. A test of the effect of neostigmine on salivation (the best method available) could be tried both by tablets and by injections. Thyroid could be tried, if not already in use.

The theory that oral symptoms originate from a difference of electrical potentials between fillings of the teeth has not held up well. The symptoms due to such a condition have been described as prickling and burning, usually in certain areas, rather than a dryness.

Specialists who have recently published articles on oral medicine include two Philadelphians, Samuel Bradbury, M.D., Pennsylvania Hospital outpatient department, and Lester W. Burket, M.D., D.D.S., professor of oral medicine, University of Pennsylvania Dental and Post-Graduate schools.

EPINEPHRINE INHALATIONS FOR ASTHMA

To the Editor:—What are indications, dosage and dangers of 1:100 epinephrine inhalations for bronchial asthma in a 4 year old child?

M.D., New York.

Answer.—The indications for inhalation of 1 : 100 epinephrine for bronchial asthma in a 4 year old child are practically the same as for an adult. Such treatment is not as successful in children. Epinephrine inhalations are indicated where quick results are desired, with the minimum of side effects such as is obtained from oral or hypodermic medication, and where self medication offers an advantage. The greatest handicap to its use is the poor cooperation from youngsters of that age. The dosage of inhaled epinephrine is usually measured in terms of the number of compressions of the bulb of the nebulizer. With the usual nebulizer one to six squeezes of the bulb are required to nebulize sufficient drug to produce the desired effect. In practice this is determined for each patient and with each particular apparatus. When the effective dose is determined, this may be repeated in an hour or two. Excessive use of such epinephrine spray may cause sufficient absorption to result in tachycardia and nervousness as with hypodermic injection. It may also produce pharyngeal, nasal and gastric irritation.

INDICATIONS AND DANGERS OF SPINAL AND CAUDAL ANESTHESIA

To the Editor:—What is the status of caudal and spinal anesthesia in obstetrics? Have many hospitals banned its use because of sequelae such as backache or headaches or other untoward reactions? What dangers are there and how well qualified should the physician be who uses the method? Should this procedure be attempted by the general practitioner?

M.D., New York.

Answer.—There has been little change in the status of caudal and spinal anesthesia in obstetrics. Spinal anesthesia has an established place in obstetrics. The use of caudal anesthesia, after the recent tremendous interest and enthusiasm for it, professional and nonprofessional, is finally receding to take its proper place as a method of choice in anesthesia for obstetrics. It has its indications and, just as spinal anesthesia, its dangers. Either method requires technical skill, careful supervision and an adequate knowledge of each technic to lessen such sequelae as backache, headache and paresthesias. When properly administered, the aforementioned sequelae are rare, especially with the low anesthesia usually desired in obstetrics. In many of the larger institutions with adequately trained personnel, caudal and spinal anesthesias are methods of choice. In most hospitals the use of either method by inexperienced personnel is discouraged. In a few it is prohibited. These methods of anesthesia should not be attempted or routinely practiced by the general practitioner.

PROCIDENTIA

To the Editor:—A woman who weighs 300 pounds (136 Kg.) and has had five children now has a bothersome procidentia. She has had a subtotal hysterectomy and after repeated childbirth has little support from the perineum. She has tried wearing a pessary but reports that it is too irritating. Will a perineal repair give relief, or is some other procedure more desirable?

F. M. Middlebrook, M.D., Dalhart, Texas.

Answer.—A woman like the one described in the query might be relieved of symptoms by a Manchester operation combined with the necessary repair of the perineal damage.

BONE GRAFT FOR LEUKEMIA

To the Editor:—A white boy aged 8 years has been hospitalized for leukemia. The attending doctors state that he can live for only a few months. Would a bone graft be of value, for example into one or both tibias?

M.D., Pennsylvania.

Answer.—Transplantation of small amounts of marrow, obtained by sternal puncture from normal, compatible donors, has been tried in the treatment of leukemia but usually without clinical improvement. A five year remission has been reported in 1 patient (Shiro, H. S., and Weiss, H. B.: Acute Monocytic Leukemia, *Am. J. Med.* **1**:307 [Sept.] 1946).

There are no successful reports of bone grafts in leukemia. The danger of hemorrhage and infection makes the operation hazardous.

PREGNANCY AND LIBIDO

To the Editor:—A woman aged 21 has been pregnant for five months (primipara) and complains of complete loss of orgasm during coitus and increasing frigidity. Is this due to the pregnancy? M.D., Bronx, N. Y.

Answer.—As far as known, female animals do not permit coitus during pregnancy. Human beings, of course, do indulge in sexual intercourse during gestation. In most instances there is no interference with the normal libido. In fact, in some instances because of the absence of mechanical contraceptives and the removal of the fear of an unwanted pregnancy the desire and satisfaction are increased. On the other hand, many women lose their sexual desire and ability to have an orgasm and in some instances there is actual revulsion to coitus during pregnancy. In most cases there is a return of normal libido after delivery. If the libido does not reappear, there is usually a psychic reason.

DDT POWDER FOR FLIES

To the Editor:—The problem of use of DDT as it presents itself to Dr. Clarke in Queries and Minor Notes of Jan. 4, 1947 and to many others who use the insecticide can be resolved quickly if this simple method is used: Throw a small quantity of the dry DDT *powder on the floor* at a point where traffic is heaviest. Walking feet will spread the insecticide effectively. Flies will land on the floor often enough to make contact with the poison. Complex solutions and spraying are unnecessary. I have found that a tablespoon of the high concentrate powder thrown on the floor of any army barracks building is exceedingly effective in reducing the living fly population in that building.

THE AMERICAN PHYSICIAN IN 1846 AND IN 1946

A Study in Professional Contrasts

RICHARD H. SHRYOCK, Ph.D.
Washington, D. C.

Centenary celebrations afford a natural occasion for comparisons of the old and the new. The century which has elapsed since the Northern Medical Association of Philadelphia was founded in 1846 was one in which most aspects of civilization changed with unprecedented rapidity, and medicine was no exception to this rule. Hence the contrast between the status and activities of the American physician in 1846 and in 1946 involves much that may seem unusual to the modern observer.

The glance backward may also reveal some things which are of more than antiquarian interest, for certain problems persist even through a century of change. The most commonly aired grievance of American physicians during the 1840's, for example, was the difficulty of collecting fees. "It runs me almost crazy," wrote a successful practitioner about 1840, "to think that with hundreds upon hundreds due me professionally I find the greatest difficulty in raising a simple fifty dollars."[1] No doubt there has been improvement in this respect; but rumor has it that even now there is occasionally some difficulty of this sort, and the whole matter of professional income is involved in current discussions of health insurance. The earlier experience of members of the medical profession with this or with any other persistent problem invites comparisons which may throw light on contemporary situations.

Many who contemplate the past—and who does not do this occasionally?—go to one of two extremes. Some accept uncritically the modern faith in progress and assume that everything was pretty backward until they came along, while others reverse this attitude and succumb to a nostalgia for the good old days. In 1925 a Maine physician wrote this inquiry: "I wonder if the medical man is held in as high esteem, or is as important a factor in the community, as was his confrère a half century ago?" The reply was a negative one: the questioner was convinced that the doctor of 1875 had much the better position.[2]

For a real answer to his inquiry, of course, one must examine the evidence. A wealth of material immediately appears, pointing in the opposite direction. Whether one sticks to the seventies or goes back to the forties makes little difference, for a definite improvement in the status of members of the American medical profession did not set in until almost 1900. There were no public opinion polls then, by which to measure attitudes toward a profession; but the difficult position of physicians may be easily illustrated by random references. The newspapers of the forties and fifties, for example, sometimes ridiculed medical students and medical practice. Occasionally they went to extremes of condemnation. Thus the Philadelphia *Item* denounced (1858) the "poisoning and surgical butchery" which were common in practice,[3] while in the next year a large daily paper declared that the whole medical guild was "a stupendous humbug."[4] Many lay critics had as low an opinion of professional behavior as they had of professional skill. "It has become fashionable," declared the editor of the *Cincinnati Medical Observer* during the fifties, "to speak of the Medical Profession as a body of jealous, quarrelsome men, whose chief delight is in the annoyance and ridicule of each other."[5] Alarmed by such attitudes, physicians had begun in the thirties to deliver addresses on "The Present Position of the Medical Profession." Two decades later they employed such frankly discouraged headings as: "To What Cause Are We to Attribute the Diminished Respectability of the Medical Profession in the Estimation of the American Public?"[6]

It is clear, after even such casual glances at the record, that all was not well with the profession a century ago. Granting that there still may be some cynicism about medicine, it is hard to imagine a daily paper referring to current surgical intervention as mere "butchery," or condemning professional practice as "a stupendous humbug." Compare with these epithets, for example, the respectful manner in which both contemporary newspapers and movies usually deal with physicians. About a decade ago there was a series of films which portrayed medical personnel in almost glamorous colors. These were embellished with such titles as "Men in White," "Women in White," "The White Parade" and so on. For a while anything "in white" was good for boxoffice returns. There were also such laudatory pictures as "Pasteur" and "The Magic Bullet," to say nothing of the late lamented "Dr. Kildare." If Hollywood is to be trusted, the medical profession has today a far higher position in public esteem than it did in great-grandparents' days.

To what circumstances may one attribute the uncertain status of physicians a century ago? There is no one simple answer to this, any more than there is a single explanation of professional prestige at the present time. Various factors must be noted, if one is to understand the position in which physicians found themselves at the time this association was founded.

In an analysis of the status of any profession, one first thinks of the original process by which personnel is selected. One envisages today the years of college education and the standards of grade A medical schools, all of which tend to prevent the lazy or incompetent student from taking the Doctor of Medicine degree. But in 1846 almost any man with an elementary education could take a course of lectures for one or two winters, pass an examination and thereby automatically achieve the right to practice medicine by state law. Since the old training under an experienced physician (preceptor) had been gradually abandoned, doctors could be turned out in less than a year. As late as 1900 there were medical schools which admitted students who could not gain entrance to a good liberal arts college. To be sure, some college graduates went to the better medical schools; but a study made at Yale in 1850 indicated that most graduates preferred law and theology, and that those who did enter the field of medicine were usually not of high standing in their classes.[7]

It would be of interest to inquire, in passing, whether the first women to secure medical education were of superior caliber. One might expect this, in view of the opposition they had to overcome. Most physicians and laymen were shocked at the very thought of a "doctress"; but after the Woman's Medical College was opened in Philadelphia in 1850 some newspapers encouraged the idea, and there was occasional support even in the medical journals.[8]

Whatever standards were maintained by the few "female" colleges, most schools admitted youths without higher education and with uncertain secondary school backgrounds. In 1854 a candidate requested admission to the Savannah Medical College on the impressive ground that he was proficient in the use of his own language. A professor in reply said that it would help if the student also knew something of the classics but added hastily that he could pick this up "with perfect ease" while attending the lectures. The student was invited to enter and reminded that he could not find a better college in that part of the country.[9]

This last remark was significant. The Savannah College was apparently a proprietary school, even though a superior one, and the practitioners who owned it needed the tuition fees. By 1850 the original university schools were pressed by the competition of proprietary institutions that sprang up all over the country. This proliferation has been ascribed to the increase of population and the consequent demand for more practitioners than the old schools could supply. But since the country already seemed oversupplied with physicians by the fifties other influences must have been at work. The late Dr. William H. Welch believed that the English medical schools (without university connections) set a bad example here. But the London schools were at least associated with hospitals, while American institutions sometimes lacked this advantage. The truth is that there was money in a successful medical college, since the owners maintained it simultaneously with their private practice. The lower the standards, outside a few main centers, the higher were the registration figures and the profits. No wonder that schools multiplied, and that intense jealousies developed between the members of rival medical faculties.

Competition from mediocre schools hurt even the better institutions. When Pennsylvania tried to raise its entrance and course requirements during the forties, many youths were reported to be leaving for "easier quarters." The editor of the *Item*, already quoted, declared that even the Philadelphia students were coarse, crude and ignorant; a New York paper added the adjective "licentious" in describing the young medicos of that city.

Due allowance may be made for editorial exaggeration in such statements. But since they were supplemented by ample testimony from leading medical practitioners themselves, it is clear that the recruitment of the members of the profession was a rather casual process. This was of grave concern to professional leaders, and their efforts to form state medical societies were motivated in part by the effort to reform medical education. This was desired not only to provide better training per se but also to overcome the jealousies of rival schools. The same motives inspired the founding of the American Medical Association in 1847.[10] The national body encountered great difficulties, however, in seeking reform. Influential practitioners throughout the country were interested in proprietary schools and opposed standards which would have eliminated them. When Oliver Wendell Holmes, for example, condemned what he termed "inferior schools, wrongly located," he raised a storm throughout the South and West. Medical professors in those areas viewed this as a sectional attack on themselves and ridiculed Holmes's "highfalutin Boston notions."

Tied in with low standards in the schools was the general laxity of state licensing laws. Early in the nineteenth century certain states had enacted fairly good statutes, which provided for examination by state medical societies or boards. But it proved simpler to license automatically all who graduated from the schools; and as the latter deteriorated, licensing became almost a farce. Some reformers advocated federal licensure,[11] while others considered that the M.D. degree had become meaningless and urged that it be replaced for able men by some such designation as M.A.M.A. (Member, A. M. A.).[12] This would not control licensing, but would at least indicate the real physicians. Such protests achieved little until almost the end of the century, when the impact of scientific progress enabled the national Association to initiate a really effective reform movement.[13]

Another problem which faced medical societies a century ago was the relation of one practitioner to another. After the student had taken his degree, such as it was, he found himself in sharp competition on entering practice. By 1860 there was 1 practitioner for every 572 persons in the population as a whole.

[13] The detailed story of medical education before 1860 is given in Norwood, W. F.: Medical Education in the United States Before the Civil War, Philadelphia, University of Pennsylvania Press, 1944.

The ratio was apparently higher in rural than in urban areas—just the reverse of the present situation. The rural physician was then in great demand and suffered few such disadvantages as he does at present. In the North (relatively urban) there was 1 physician to 534 inhabitants; in the South, 1 to 526, and in frontier states, 1 to every 417. The general average of 1 to 572 may be compared with that of 1938, which was 1 to 764.[14] The excess of physicians was such that many young graduates failed to secure a decent practice and abandoned the profession. The pressure of competition not only caused bitterness against sectarians but also created friction within the regular profession.

Prior to about 1800 there had been no rules to the game, and physicians even condemned one another in the newspapers. A famous illustration of professional friction in Philadelphia had been Benjamin Rush's newspaper debate with colleagues over the best methods of treating yellow fever. Laymen took sides, and in the course of this debate one critic referred kindly to Rush's method as "one of those great discoveries which are made from time to time for the depopulation of the earth."[15] Rush denounced his colleagues, resigned from the College of Physicians and viewed himself as a much-abused figure. This was typical of many professional quarrels.

These difficulties were not to be entirely explained by the competitive factor. This affected lawyers and business men as well, yet physicians were notorious for the peculiar rancor of their quarrels. Perhaps the vital nature of medical work made for unusual bitterness between rivals. Many a doctor, at a time when medicine was much more of an art than a science, honestly believed that competitors were killing their patients rather than curing them. Or, if the rival was not actually liquidating his clientele, he was doubtless doing them no good and overcharging them in the process. The welfare of the public as well as self interest demanded that he be exposed.

It was gradually realized, however, that the scandal of medical quarrels was injuring the reputation of the profession. Even Rush, a born controversialist, sensed this in his last years. He then pleaded that physicians should cease to condemn one another just because of different theories of practice and urged that "the whole odium of the hostility of physicians" be ascribed to "their competition for business and money."[16]

Medical societies, fully aware of the frictions resulting from competition, sought to standardized principles of professional behavior. Percival's "medical ethics," adopted in London toward the end of the eighteenth century, was the basis of the code accepted by the American Medical Association at the time of its founding, and this English statement was also largely incorporated in the principles accepted by state and local societies.[17] These codes expressed certain general ideals and stated the duties of physicians to patients, to each other and to the public. They have since been criticized as providing "trade union rules" or "books of etiquette" rather than true ethics. Some critics object to the limitations set on criticisms of one physician by another, lest these shield the mediocre man at the expense of his patients. The codes may need overhauling today to fit them to modern conditions,[18] but any one who recalls the time when physicians did boast openly of their own merits and of the inferiority of their rivals will recognize the real service which these statements provided.

Even after medical societies had been organized there was no little recrimination within the profession. In 1851, for example, the therapeutic claims of a certain physician were attacked on the floor of a state society. In retaliation the man then published a pamphlet referring to the "meanness and baseness" of the society's procedure, adding that the state organization contained only "the pest boys and inexcusable ignoramuses" of the profession. A member of the society, writing to a colleague, began by inquiring: "Have you seen the dirty pamphlet of Dr. X? . . . The more I reflect on this man's attack on the state society the more angry I feel. . . . After I read his account of pneumonia and his never having lost a single case out of 179! I might have swallowed his 'obstetricy' (where did he get that word?) but I choked at his pneumonia statistics. . . . I wish no controversy with such a man . . . but I shrink from no responsibility."[19] One can see from such correspondence that the officers of early medical societies had their hands full in preserving professional harmony.

Long before ethical codes were adopted the early medical societies had sought to deal with the strictly economic factor in competition. They realized, apparently earlier than did business interests, that uncontrolled competition in an entirely free market was not in the interests of competitors. Perhaps the guild tradition in medicine had never permitted the acceptance of a *laissez faire* philosophy so extreme as that embraced by merchants. At any rate, a prime motive in the founding of the pioneer state medical society (New Jersey, 1766) had been the standardization of fees. The fee bill issued by that society listed charges of 25 cents and up for calls in country practice, according to mileage, and such other items as $3.50 for deliveries. When it is recalled that annual tuition at Princeton was then only $4, these charges seem by no means low.[20]

Much the same comment may be made on the fee bills published by medical societies about seventy-five years later; that is, for the era just before the Civil War. Between 1835 and 1860, a fee of 50 cents or $1 was common for an office call at the physician's home in town practice, and rates were higher in the large cities.[21] These charges were at least the equivalent in purchasing power of $2 to $5 at the present time. Such comparisons are difficult to make for home

calls, because the physician then charged in proportion to the distance traveled. The rural doctor also charged for medicines, so that it is hard to isolate the costs of professional services from those for drugs. Thus Dr. Tomlinson Fort of Milledgeville, Ga., included such items as the following in bills for 1841:[22]

Visit, 4 miles in rain, and med.	$ 7.00
Visit, nocturnal, 4 miles	8 00
Visit, 4 miles, $5.00 med., for gonorrhea	15.00

If one at least doubles these figures in order to estimate their purchasing power today, the fees seem relatively high.

Due allowance must be made here for certain variables. Dr. Fort's bills went to a planter who was probably wealthy and was perhaps charged accordingly. Bills sent to the rank and file may have been lower. Actual charges to most patients, moreover, were sometimes less than those stated in the fee bills. There were complaints to this effect, for a published schedule was after all only a gentleman's agreement. But, keeping in mind all these factors, it seems likely that fees in general practice a century ago were little if any lower in real value than are current charges.

This is surprising when one recalls, first, how low the costs of medical education and equipment then were; and second, the common impression that rising professional costs have forced fees up since that time. Present protests against medical costs are not caused by higher fees in general practice but result rather from the many specialized services now required.

Had the average total cost of medical care been as high in 1846 as it is at present, it would have been quite impossible for the great majority of patients to have met it. The average, per capita real income then was less than half what it is today.[23] In other words, the ability to maintain present levels in medical costs—even as well as is now done—results from improvements in living standards all along the line.

Total medical costs were relatively low in 1846 because most persons were served simply by the family physician. Those in and near towns could reach pharmacists and dentists, and they occasionally resorted to consultants; but most rural folk, who then made up about 85 per cent of the population, received only bills for office or home calls from a single physician. Many of these charges, moreover, were not paid—a simple way of keeping down medical costs.

Difficulties in collecting fees inclined some physicians to accept so-called "contract practice." A physician would care for a family in return for a fixed payment in advance, perhaps for as little as $5 or $10 a year. There were then few opportunities for salaried positions, and contract work may have appealed to practitioners in need of income. Similar procedures were sometimes followed in Europe, where they had had a long history.[24] The arrangement involved the prepayment principle for families only as a matter of individual agreement; whereas the insurance of entire groups, basic to current prepayment plans, was not introduced into American insurance until after 1910.[25] Just how extensive contract practice was in the United States before the Civil War is difficult to say, for one learns of it chiefly through objections voiced by professional leaders, who viewed the arrangement as demoralizing. It is doubtful if it was ever widely followed.

While on the subject of finances, one may well raise the old question: Why did the doctor's bill come last? The butcher, the baker, the candlestick-maker—all these must be paid promptly, but not the physician. Doctors themselves were none too meticulous about these matters, and many of them asked for settlement only at year's end. If not met then, the account was likely to go over another year, and so on. One of Dr. Fort's bills, noted previously, totaled $73.75. Under this was added the laconic statement: "8 yrs. int., 8 %, $47.20."

The answer to the question just posed probably lies in the conflicting traditions of the profession. From the Middle Ages was inherited a semiclerical status—physicians should be more concerned with service than with profits. Hence arose the obligation to give freely to the poor, a generosity which was rarely expected of merchants. But modern capitalism had involved physicians in a competition for income which could not be ignored and which they tried to reconcile with the service ideal in ethical codes already mentioned.[26] The public, although it recognized medical charges as an obligation, tacitly assumed that these would not be pressed. Was not the physician the friend of the family, and was not this relationship above mercenary considerations? Professionally speaking, the practitioner thus lived a double life—half benefactor, half business man—with all the difficulties this entailed. The basic problem remains today, though it seems less acute under prevailing urban forms of practice.

Close personal relations between physicians and patients reflected both scientific and social conditions. Medical science, as will be noted later, then had small bearing on therapeutics. Hence few physicians felt it necessary to give much time to current scientific developments. They were, on the other hand, under constant pressure to meet the immediate needs of their neighbors. The established practitioner in a small urban or rural environment knew the lives of his patients and the affairs of the community. There was continuity in practice, for he had brought his patients into the world and seen their fathers out of it. Other things being equal, these circumstances were of real advantage in his work. The good family physician sensed environmental and personal factors in illness: he was his own medical social worker and authority on psychosomatic relationships. Mr. X would not be sick, his doctor would remark, if he could lift the mortgage on his farm. Mrs. Y's case needed what no one could give her—the return of her lost child. The physician would use either bread pills or bitter doses if these were indicated by personal factors. Most important on the psychic side was the influence of his own authority and personality. Here he was aided by the almost instinctive desire of patients to have faith in the man to whom they entrusted their lives.[27]

[25] Sickness benefits paid to members by lodges or mutual benefit societies, however, may be viewed as anticipating present group health insurance

[26] Sigerist, H. E: Medicine and Human Welfare, New Haven, Conn. Yale University Press, 1941, p. 116.

Although there was a growing tendency after 1830 to distrust medical science in general, even the person who shared this feeling was apt to believe that his particular physician could always be of help.[28] Such faith, when misplaced, might have tragic consequences. Amid all the praise of the old family doctor it must be remembered that when incompetent he was of little use and may at times have done considerable harm. But faith in a competent man had its merits. The nice question, then as now, was how to distinguish between the able and the mediocre practitioner. Only in or near towns could there have been much range of choice, and in such locations the personal factor and sheer accident must have played major roles in the selection of family physicians. Hospital or medical school connections, often urged today as indications of professional merit, were then less significant or simply nonexistent. Graduates of certain schools seem to have had a superior reputation in special sections, as those of Harvard in New England, of Columbia and of Bellevue in New York and adjacent states, and of Pennsylvania and Jefferson in the Middle Atlantic area and the South. One authority at Yale suggested that patients, in considering a man as a prospective family physician, should engage him in conversation. If he spoke well on general matters the chances were that he was also intelligent in his practice. Beyond this there seems to have been little consideration of a problem which was so vital to the individual layman.[29]

Once having selected his physician, the American of the early nineteenth century was likely to place the greatest trust in him. Contemporary physicians might well envy the Dr. Watkins mentioned in the following note, in view of the naive confidence displayed by his patient. The latter was Miss Virginia Randolph, a granddaughter of Thomas Jefferson and an intelligent and cultivated young woman. In a letter to her fiancé in 1822 she confided that:[30]

> We have had a rather sick family lately . . . and I am on Dr. Watkins' list. He has bled me twice, and prescribed a course of calomel which I am getting safely through . . . and I expect soon to be perfectly restored. You must not expect . . . that my health is worse than it frequently is, in summer, but Dr. Watkins wishes to make a permanent cure at once of all my complaints. . . . I have no doubt that his advice is most judicious.

The cynical reader will observe that it was the "course of calomel" rather than the illness which the patient was "getting safely through," and will no doubt marvel at Dr. Watkins' determination to cure *all* her difficulties *permanently* and *at once.* Yet Miss Randolph was probably none the worse for her faith in this case, and perhaps it sustained her in later and more serious "complaints."

The successful physician was then, as now, an overworked man. In the case of the city practitioner this was a matter of many patients—particularly if he were associated with a hospital. "The average of my private patients in the late summer and fall months," wrote a physician in 1849, "is generally between 30 and 40, and to get through with these . . . I am going the round from sunrise to 9 or 10 o'clock at night." In addition, he saw daily from 60 to 70 hospital patients. "The profession," he added on another occasion, "is one which certainly requires that a man should give up almost every social enjoyment and is therefore one which a person like myself who has so keen an enjoyment of such pleasures ought never to have chosen."[31]

This does not mean that all physicians were denied social diversions, though clearly their evenings were not as free as those of other men, and they had little time for political activities or public affairs. Lawyers could run for legislature or Congress; physicians seldom had the time. In the large cities, however, prosperous physicians enjoyed the social life of medical clubs. One of the two original secretaries of the American Medical Association, en route to the organizing meeting in 1846, wrote as follows of professional hospitality in Philadelphia:

> This is a delightful House. . . . The assortment of wines, sherry, sauterne, champagne, and madeira was delicious. . . . After dinner we went to the Opera. . . . We were obliged to lose the third act, to go to Dr. Bell's Medical Club. The physicians here are very sociable amongst each other and meet three times a week at each other's houses. . . . We returned to the Opera and heard the third act and after that Dr. Clymer took me to the Club . . . I had an idea that they were all as stiff as if done up in buckram, but at this club, which is held at a large house in Walnut Street occupied solely by it, [there are] reading rooms below, card rooms and supper room on the second floor and billiard rooms on the third. I met Drs. Wm. Rush, Randolph, Biddle, Gerhard and Fox. . . . Without knowing it I played a game of five-dollar whist, but as soon as I was square I stopped playing.[32]

The country practitioner had no such opportunity for professional sociability, and such diversions as he had were those of the community at large. However, his lack of contact with colleagues was nothing like the deprivation that this seems today in isolated areas. The nature of practice was so simple that there seemed little technical need for a hospital or for professional discussions. Deliveries were made at home, and the kitchen table still seemed adequate for emergency surgical procedures. Incidentally, the introduction of anesthesia in the late forties aided surgical practice in country homes as well as in city hospitals.

The rural physician handled all phases of practice, including pharmacy and dentistry. While he saw fewer patients than did his urban colleague, he was kept just as busy by long hours spent on the road. It is not easy to picture this old routine, though much has been written about "the horse and buggy doctor." As a matter of fact, the buggy was not the only means of transportation. The physician often rode an old mare equipped with saddlebags which contained drugs and a surgical kit. He was on the road so much of the time that he could have no regular office hours: patients must take their chances on finding him at home. When a railroad reached a community, the physician would use that if possible, sometimes being extended the doubtful privilege of riding the freight cars. Occasionally he even sallied forth on a "railroad tricycle."

similar to the later handcar.[33] These devices, like runaway horses or modern automobiles, had their own peculiar risks.

One form of practice was peculiar to the days before the Civil War. This was the care of slaves. On southern farms of moderate size practice was usually in the hands of the mistress or of overseers, who were guided by tradition and by family medical manuals. Dr. Samuel Cartwright referred in 1850 to "the practice among 3 millions of people [Negroes] that the overseers have mostly got." [34] Even slaves themselves occasionally acquired a reputation as folk practitioners.

It was argued in defense of slavery that it gave the master a financial interest in preserving the health of his "people," and this was doubtless true in the case of the more enlightened and prosperous planters. Such men would hire Irish laborers rather than put their slaves into dangerous work. If a slave died, there was a loss of several hundred dollars; if an Irishman perished, there was just one less Irishman in the world! [35]

Wealthy planters would regularly employ a prominent local physician to look after their plantations. This gave slaves as good care as was then available and provided them with a rough equivalent of modern health insurance. There were certain legal aspects here which were peculiar to slavery. In cases which required surgical intervention, for example, the master's permission rather than that of the patient was required. (In one curious instance the great gynecologist Marion Sims could not secure such permission and actually purchased a patient in order to operate on her.[36]) After emancipation most of this service was lost, and the rural southern Negro now receives less medical care than do members of any other large element in the population.

Implicit in all that has been said is the fact that nearly all physicians in 1846 were general practitioners. Certain persons became especially interested in surgery, but they seldom abandoned general practice entirely. This combination of the physician and surgeon in one practitioner came down from a time of primitive colonial conditions, when differentiation would have been impractical. As a result surgery always maintained equal prestige with internal medicine, in contrast to the professional and social distinctions which had been traditional in Britain.

It is usually assumed that specialization was lacking at this time simply because there was not enough knowledge to justify it. This was indeed one factor in the situation. But there was another basic explanation. Prior to about 1830, American physicians did not usually think in terms of a localized pathologic process or of specific diseases. Speculative pathologies had dominated medical thought up to that time. All forms of illness were ascribed to one or two generalized conditions, such as impurities of the blood or the existence of excessive tension or laxity in the nervous and vascular systems. These were appealing theories, since they solved all pathologic problems at once and also opened up a royal road in therapeutics. If all illness was due, as Benjamin Rush claimed, to excessive tension in the blood vessels, then all patients could be cured by bleeding to relieve that tension. Any one could see that if the patient was bled long enough he would relax—sooner or later! Hence the physician should put no faith in the healing powers of nature but rather should interfere with nature as promptly as possible.

As long as all forms of illness were viewed as expressing a single, underlying condition, there was no occasion for specialization in practice. Every physician considered that he had the remedy that was "good for what ailed you," since by definition the same thing ailed every one. Incidentally, there was also no use for major surgical operations, for one could hardly operate on the blood or on a vague condition common to the whole vascular system.[37] Hence surgical practice remained largely a matter of fractures, amputations and other superficial emergencies, and here again there was little need for specialization.

Only when a localized, structural basis for pathology replaced the speculative systems was specialization made possible. When specific diseases were identified by correlating lesions with symptoms, the possibility of treatment by removing these lesions became obvious. Surgery, was therefore beginning, by 1840, to move from the periphery toward the center of medical practice. And there was now some reason for specializing, in other fields than surgical practice, in work on a particular part or system.[38] But these new points of view, imported from Paris by returning American students after 1820, percolated slowly into average practice. Not until after the Civil War did specialization really get under way, even in the cities.[39] There was strong opposition at first, partly because of the fear that it would injure the interests of both patient and practitioner; [40] partly because in the earlier day only quacks had claimed to specialize. Dr. S. Weir Mitchell could recall the time in Philadelphia when to specialize meant to be professionally ostracized.[41]

The French school of 1800-1850 was as critical of the traditional therapeutics as it was of the older pathologies. Since it identified diseases by symptoms as well as by lesions found at autopsy, it developed methods for improving clinical observation. The stethoscope and clinical statistics are cases in point. But the use of the latter showed the ineffectiveness of bleeding, purging and the old drugs. Hence French clinicians gradually lost interest in therapeutics. How could there be an *intelligent search for the causes and cures of diseases* until the diseases themselves had first been found?

Medical research thereupon became nihilistic; it was focused on diagnosis rather than on treatments. The latter were viewed as useless in most cases. Oliver Wendell Holmes, on his return from Paris, informed the American people that if most of the medicines used here were thrown into the sea it would be all the better for mankind and all the worse for the fishes![42] What was needed, he felt, was less medical interference and a revived confidence in the healing powers of nature. This critical view affected average practice only after a long interval; indeed, Osler was still preaching it in the first edition of his textbook near the close of the century.[43]

It is true that by the fifties some younger physicians indoctrinated by French-trained professors were becoming less inclined to bleed and purge, less given to excessive medication. But most practitioners clung to traditional forms of treatment. Some of the older men, even those who taught in the better schools, were still defending venesection in the seventies.[44] This half century lag in bringing practice into harmony with research is an interesting phenomenon which has never been adequately studied.

In reaction to such professional conservatism, popular opposition developed against heroic treatments. Such was the protest against calomel (mild mercurous chloride), for example, that a large and thriving medical sect—the Thomsonian or "Botanic System"—based its appeal on the condemnation of all mineral or metallic remedies that had come into use since the days of Paracelsus. Echoes of its propaganda survive today in the advertisements of secret remedies that "contain only vegetable compounds."

Popular distrust of medical treatments was based, by 1840, on more than a dislike of unpleasant or dangerous remedies. By this time physical science was making such headway that all could appreciate it. But where were the *medical* equivalents of the steam engine or the telegraph? Medicine seemed to have fallen behind the other sciences: indeed, the leading professors of medicine now admitted that their science was of little utility. Perhaps the old medical "systems," with their speculative pathologies, were really more valuable. They had at least promised cures. So encouraged, various theorists revived the doctrine that there was one cause and therefore one cure of disease. Thus Hahnemann reduced most pathologic conditions to the itch and most treatments to the "like cures like" theory and the high dilution formulas, somewhat as Dr. Still would later reduce all pathologic processes to spinal conditions and all therapeutic practice to spinal manipulations.

Regular medicine, which had accepted such oversimplifications in Rush's day, was now more critical and would have none of them. Homeopaths and Thomsonians thereupon became the modern medical sects. They founded their own schools and journals and so contributed to the confusion in education and licensing which has previously been mentioned.[45] On the other hand, the sects probably did more than did French nihilism to create a salutary demand for milder treatments.

The more credulous or nervous folk also flocked to a whole series of minor cults which promised sure and pleasant cures. Nearly every conceivable type of humbug preyed on the people—hydropathy, chronothermalism, mesmerism, herb doctors, faith doctors, indianopathists and what you will! Meanwhile national advertising in newspapers was originated by the manufacturers of secret remedies, and more money was spent for nostrums than for prescriptions. When regular physicians protested, they were viewed merely as opposing competitors. Was not this a free country, and did not every American have an inalienable right to life, liberty and quackery? A writer in one of the journals of opinion suggested that "the public will act as an umpire" between the regulars and the sectarians, and reach its decision "after a careful perusal of the undertaker's bills."[46]

It is to be recalled that this was an age of social ferment and reform, the day of the great temperance, antislavery and women's rights movements as well as of minor utopian aspirations. "We learn from the papers," observed Dr. William Alcott in 1835, "that the American Seventh Commandment Society, the New York Female Benevolent Society, the New York Ladies' Moral Reform Society, and the Anti-Tobacco Society held their annual meetings at New York about the middle of May, and that some of these meetings were interesting."[47] In such an atmosphere it was natural that a utopian health cult should arise, advising all to maintain health by staying away from the physicians and by cultivating personal hygiene. Their views represented the logical extreme of the "trust nature" philosophy, which was preached in more moderate form by physicians who had been influenced by French nihilism. Sylvester Graham, the leader of the cult, preached during the forties the virtues of bathing, of exercise and of a whole-wheat diet. In his spare time he originated an interesting literary tradition later known by the phrase "What a Young Man Should Know." His antimedical doctrine was spread by "Ladies Physiological Reform Societies," and he is unconsciously recalled to this day in the terms "Graham bread" and "Graham crackers."[48]

The appeal for personal hygiene had some merit at a time when the Saturday night bath was a real victory for sweetness and light. But more significant was the public hygiene of the period. About the end of the eighteenth century, the medieval doctrine of contagion in epidemics was partially replaced by a revival of the classic "airs and waters" hypothesis. If epidemics originated in the local contamination of air and water, then quarantines were of little use. "Noxious Miasms" could be eliminated only by cleanups, by sanitary reform. Philadelphia led the way, after its bitter experiences with yellow fever, in constructing one of the first steam-powered water works in the country (1802) and by other municipal improvements. Bitter controversy continued, however, over whether certain diseases were spread by miasms or by contagion.

---

[42] Holmes, O. W.: Currents and Counter-Currents in Medical Science, Boston, Ticknor & Fields, 1861, p 39.

[43] By that time such nihilism was almost out of date, for pharmacology and bacteriology already held real promise for both prevention and cure.

[44] I. e., as a general procedure in many forms of illness See, e. g., Littell, S.: Memoir of George B. Wood, Trans Coll Physicians, Philadelphia **5**: XXV, 1881. Shryock,[1] p 135.

[45] Some forty Thomsonian journals were published in the United States between 1825 and 1850. For bibliography of the sects, Shryock, R. H.: Public Relations of the Medical Profession in Great Britain and United States, Ann. M. Hist. **2**: 308, 1930 [notes 41-44].

[48] Shryock, R. H.: Sylvester Graham and the Popular Health Movement, Mississippi Valley Hist. Rev. **18**: 172, 1931.

Quite naturally, as epidemic diseases were more clearly identified, distinct causal factors were sought in terms of one of these theories or the other. Specific pathology led in turn to a search for specific etiology. Those who held to miasms tried to find poisons in the air peculiar to given diseases, while those who accepted contagion turned to the old theory that animalcules or micro-organisms might convey specific infections. Such American physicians as Daniel Drake of Cincinnati, J. C. Nott of Mobile, Ala., and J. K. Mitchell of Philadelphia wrote during the 1840s in support of the animalcular hypothesis.[49] Their views, based on an intelligent interpretation of epidemiologic data, represented more than mere speculation. But they failed to verify their theories by laboratory studies. Hence the pioneer work in parasitology and medical bacteriology between 1840 and 1870 was left largely to Europeans.

The failure of Americans to contribute much to medical science prior to the present century may be explained by a number of factors.[50] Notable was the indifference of a commercially-minded people to research that promised no immediate utility. Why should any one encourage studies in pathology or in physiology, if these were of no help to patients? Professional prestige here was acquired rather through a fashionable practice, which presumably aided the sick and at the same time bore the hallmark of financial success. Such a practice left small time for original investigations.[51]

It is true that a few physicians also acquired reputations through professorships and consulting practices, but this was by no means the same thing as research. These men edited European works, "putting British portraits of disease in American frames," and occasionally compiled textbooks of their own; but it is remarkable how infrequently even the famous professors made any systematic investigations. A committee of the American Medical Association reported in 1850 that only two "experimental memoirs" of any importance had appeared during the preceding year—one on poisons and one on the nervous system of the alligator![52]

While the American public was relatively indifferent to pure science, it was much concerned with applied science. Hence arose all the debate about medical practice and the search for immediate cures. Most pressing in the public mind was the fear of epidemics. Outbreaks of yellow fever had inspired the beginnings of sanitary reform by 1800, but it was the terrifying specter of cholera which during the thirties and again in the fifties aroused a real demand for protection. Meanwhile, municipal authorities were disturbed by the rising death rates of various communicable diseases and learned with interest of similar concern abroad. Since sanitation seemed as much a matter for engineers and statisticians as for physicians, laymen at first assumed leadership in the public health movement. Thus Lemuel Shattuck, onetime teacher, submitted an excellent plan for a state department of health in Massachusetts (1850), which was in part the basis for the state board eventually set up there in 1869.

A few socially-minded physicians realized, however, that public health programs needed medical as well as mathematical guidance. At the start of its career the American Medical Association appointed a committee on public hygiene, which submitted valuable reports on the sanitary—or rather, unsanitary—condition of American cities and called for remedial legislation.

Soon after these reports had been made, one of the leaders of the Northern Medical Association took the center of the national stage. It happened that an international sanitary conference was called in Paris in 1855 in order to discuss cooperation in quarantine legislation. This suggested to Dr. Wilson Jewell, of the Philadelphia Board of Health, that state quarantine laws were just as diverse in the United States as were national statutes in Europe and that Americans faced the same need for coordination. He therefore persuaded his board to call a national sanitary convention, which met in Philadelphia in 1857. Subsequent meetings were held, during the ensuing three years, in Baltimore, New York and Boston. Municipal officials and socially-minded physicians joined in discussions of quarantines, sanitary regulations and the need for pure food and drug laws. This principle of bringing laymen and physicians together for the promotion of health programs was later to be employed effectively by such voluntary organizations as the National Tuberculosis Association.

Jewell was the leading spirit in these first national sanitary conventions. That of 1860 planned to transform the meetings into a permanent national health association, but the session of 1861 was unfortunately prevented by the Civil War.[53] A national body was not actually formed until the American Public Health Association came into being in 1872. It would be interesting if more could be learned about Dr. Jewell, both in relation to his leadership in health reform and to his professional career in Philadelphia. It is ironic that a leader who felt he had inaugurated "a new era in the domain of American Science"[54] has been so largely forgotten in the annals of public health.

This brings me back to my starting point, the advent of this Association, for Jewell was one of its founders.[55] Evidently he was concerned with the problems of private practice as well as with those of public hygiene. Not all aspects of such practice have been considered here, but enough has been said to suggest that the physician of a century ago faced some problems that were peculiar to his time and others which persist today. The better physicians of 1846 would be proud of the present status of medical science and of the medical guild. Indeed they would be amazed by it all. The physician of today also should take a little pride in them, for they labored long under difficult circumstances to advance the interests of their patients and of their profession.

RENAL DEFICIENCY ASSOCIATED WITH SHOCK

Chairman's Address

VIRGIL H MOON, M D
Philadelphia

Many writers[1] have noted that the development of shock is accompanied by oliguria or anuria and by the retention of nitrogenous wastes, often leading to uremia if the subject survives a few days This feature is not one of the debatable aspects of shock, yet its mechanism and significance are not adequately discussed in medical literature. It has been shown[2] that shock is accompanied regularly by severe parenchymatous degeneration, especially pronounced in the kidneys; often this produces necrosis of the tubular epithelium. The possibility that these changes are related to the functional deficiency deserves thoughtful consideration.

In some instances a state of sublethal shock continues for several days; then renal deficiency often dominates the clinical picture. The urine is dark, smoky in color and has a high specific gravity. It contains albumin, hemoglobin, débris, epithelial cells, erythrocytes and casts, both granular and hyaline; frequently the casts are deeply pigmented with derivatives of hemoglobin. These features are accompanied by progressive retention of nitrogenous wastes leading to the clinical syndrome of uremia.

The occurrence of shock is not limited to trauma, burns and the aftermath of extensive surgical intervention. Harkins[3] listed more than thirty conditions in which shock may develop. These included burns, freezing, vascular occlusions, intestinal strangulation, heat stroke, radiation burns, sunburn, bile peritonitis, visceral perforations, the effects of various drugs and poisons, venoms, peptone, anaphylaxis, transfusion reactions, metabolic intoxications and infections of fulminating severity. I have reported the occurrence of shock under these and other conditions and have collected evidence on renal deficiency associated with many of them. That evidence is too extensive for detailed review here. It included, among others, Bell's[4] report on clinical acute nephritis as distinct from glomerulonephritis, Bordley's[5] and Daniels'[6] contributions on renal effects of transfusions, Lambret and Driessens'[7] studies on surgical shock, the reports of Helwig[8] and Boyce[9] on uremia associated with so-called "liver death," Christophe's[10] observations on acute nephritis as a regular feature of burns, both clinical and experimental, Bywaters'[11] observation on uremia from compression of limbs and the review of Jeghers and Bakst[12] on extrarenal uremia

The reported conditions under which acute uremia developed independent of glomerulonephritis included intestinal obstruction, toxic jaundice, hepatorenal syndrome, extensive surgical intervention, intestinal perforation, poisoning with phenobarbital, cinchophen and other drugs, streptococcic cellulitis and other severe infections, diabetic coma, Addison's disease, anaphylactic reactions, transfusion with incompatible blood, acute pancreatitis, cerebral lesions such as abscess or hemorrhage, sublethal shock from trauma as in the crush syndrome and burns.

I have confirmed the pathologic features described by others under the conditions mentioned. Grossly the kidneys may be of normal size or moderately enlarged; usually they are soft, indicating edema. The capsule strips with unusual ease; the stellate veins in the cortical surfaces are engorged. The color varies, depending on relative degrees of congestion and of parenchymatous changes. Cloudy swelling causes varying degrees of pallor; but when congestion predominates the color is deep red. Hemorrhagic streaks are seen in the medulla, and the cortical markings frequently are obscured. Petechiae may be seen in the parenchyma and in the pelvic lining.

The microscopic picture presents varying degrees of changes within a regular pattern. Usually hyperemia of the glomerular tufts and of the intertubular vessels is conspicuous. Sometimes capillary hemorrhages are present. Frequently amorphous material is seen in the capsular spaces. The epithelium of the convoluted tubules shows acute degeneration ranging to necrosis. When death occurs after several days, the cells are low or cuboidal in shape and the lumens are wide. The cytoplasm is granular; more advanced degeneration is indicated by vacuolization of the cytoplasm or by disintegration of the cells. Nuclear changes, especially karyolysis and hyperchromatism, are conspicuous.

Usually these changes are more pronounced in the upper segment, sometimes in the lower, but in general all portions of the convoluted tubules are affected. Plugs of débris often form in the lumens of the lower segments because such débris, originating in the upper portion of the nephron, collects in the narrow lumen of the lower portion. Hyaline droplets may form in the cytoplasm when degeneration is advanced; the lumens may contain masses of this deep red material when the cells containing it have disintegrated. Hyaline, granular and, sometimes, pigmented casts, débris, erythrocytes, nuclei and masses of desquamated epithelial cells occur in the collecting tubules. Edema is a varying feature, more pronounced in the medullary than in the cortical zones.

A widely known instance of this condition is the crush syndrome reported by Bywaters. Persons in buildings destroyed by explosions often were pinioned for many hours beneath masonry and débris. Some had no external wounds or broken bones, but extensive areas of flesh had been affected by continued heavy pressure. When rescued, these victims showed no serious effects except numbness and paralysis of the

compressed limbs. Presently signs of shock developed, but these were counteracted by transfusions of blood and of plasma. Even though satisfactory circulation and blood pressure were maintained, renal function did not return and the victims died of uremia.

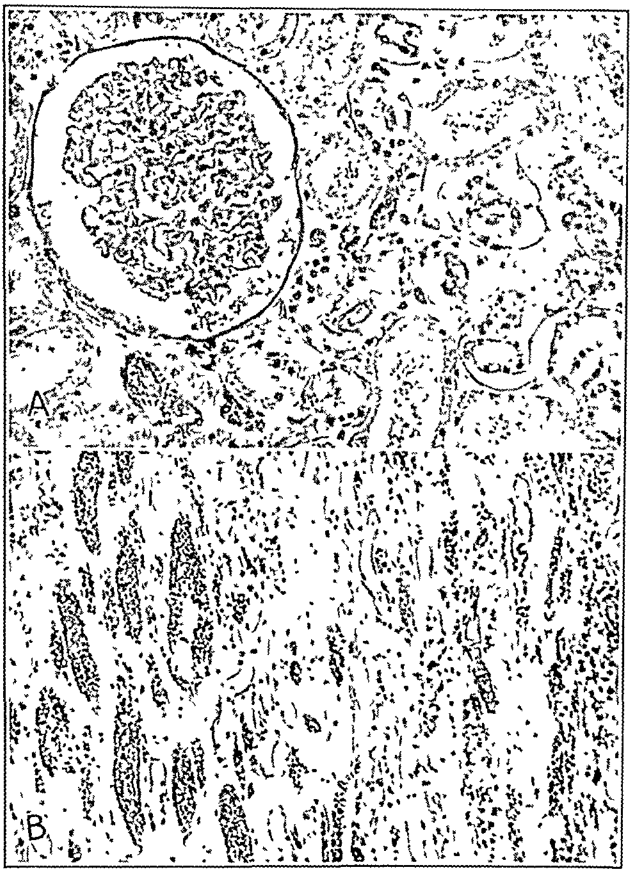

Fig 1 (case 1) —Photomicrograph (*A*) of renal cortex after traumatic shock Note the granular material in the capsular spaces and in the lumens The epithelium is cuboidal and the lumens wide, the cells show parenchymatous degeneration, and some are necrotic The nuclei are hyperchromatic, some have disappeared There are casts and desquamated cells in the lower segments of the tubules (Army Medical Museum, negative 86832) *B*, medullary portion of the same kidney as *A*. Desquamation of lining, blood casts, pigmented casts and edema are shown (Army Medical Museum, negative 86839).

The kidneys in such cases presented the picture just described. It was considered that the renal deficiency was due to mechanical blockage of the collecting tubules by plugs of pigmented débris. Were this the case, the majority of the tubules should show stoppage, and the gross size of the kidneys should be greatly increased. In sections from a patient with a typical case of shock syndrome furnished by Dr. Bywaters, only a minority of the collecting tubules were obstructed. The histologic features were identical with those resulting from surgical shock or from low atmospheric pressure (figs. 1 and 2).

Numerous instances of renal effects were found during a study of shock in the records and specimens collected by the Army Institute of Pathology. A few typical cases will be cited.

REPORT OF CASES

CASE 1.—A man aged 39 suffered lacerations, contusions and multiple fractures of the femur, ankle and ribs. He was in profound shock on admission to the Station Hospital; the pulse and blood pressure could not be determined. Transfusions of blood and fluids given intravenously were ineffective; he died of progressive circulatory failure thirty hours after the accident. The kidneys (fig. 1) show all the characteristic changes previously described, although the subject died before renal deficiency became advanced.

CASE 2—Resection of rectal carcinoma, performed under spinal anesthesia on a man aged 59, "was followed immediately by marked shock from which he did not entirely recover." Repeated transfusions of blood and of plasma did not restore circulatory efficiency. The blood pressure fluctuated between 60 and 100 diastolic. Urination was almost completely suppressed. The nonprotein nitrogen and creatinine rose progressively, and death occurred on the fourth day. The clinical diagnosis was uremia secondary to severe postoperative shock

The kidneys weighed 210 and 190 Gm.; the subcapsular vessels were engorged; the cortex was thickened, opaque and pink The tubular epithelium showed granular degeneration, decided vacuolization and beginning necrosis, which involved chiefly the upper segment. The tubules contained débris and desquamated epithelium, and there was moderate edema of the stroma.

The literature contains many observations on the renal effects of burns, so I shall give only 1 additonal example:

CASE 3.—This young man's clothing was saturated with gasoline and ignited. He sustained first, second and third degree burns of the entire body. Treatment for shock with morphine, plasma and dextrose-saline injections was begun at once; the burned areas were debrided, and pressure dressings were applied. The urine was scanty and dark; it contained albumin, red blood cells and blood casts. On the fourth day the total output was only 200 cc. of coffee-colored urine. No chemical determinations were made. Death occurred at the end of the fourth day.

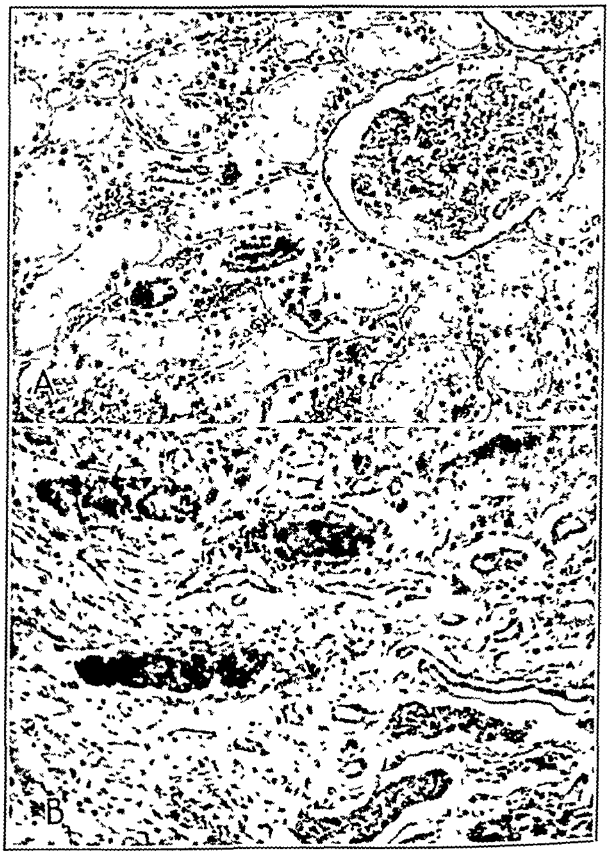

Fig. 2 (case 7) —Photomicrograph (*A*) of renal cortex after shock from low atmospheric pressure. Pronounced hyperemia, granular material in capsular spaces and in lumens, hyperchromic nuclei, degeneration and necrosis of epithelial cells, blood and pigmented plugs within the tubules are seen (Army Medical Museum, negative 86841). *B*, renal medulla from the same case. Desquamation of the lining and cellular, hyaline and pigmented casts are shown.

The visceral findings at necropsy were those usually seen after death from burns. The kidneys weighed 200 and 240 Gm, respectively; they were soft, swollen and grayish pink; the cortical markings were obscure, and the superficial vessels were engorged. Amorphous material was present in the capsular spaces; the tubular epithelium showed advanced degenerative changes; it was low cuboidal in form, and the lumens contained débris and casts consisting of red blood cells, hyaline and dark brown pigment. The color of the pigment is of particular interest because the patient had not received transfusions of blood, sulfonamide compounds or other drugs except penicillin. Evidently the occurrence of pigmented casts is not dependent on transfusion or on sulfonamide therapy.

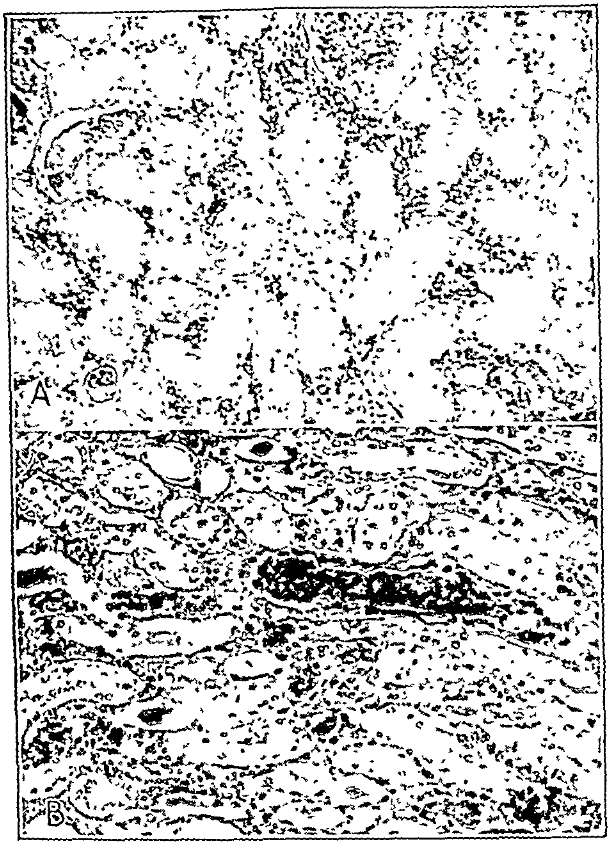

Fig. 3—Photomicrograph (*A*) of renal cortex after death from burns. Pronounced hyperemia, erythrocytes in capsular space, epithelial degeneration and necrosis, debris and pigmented plugs within the lumens are shown (Army Medical Museum, negative 89865). *B*, photomicrograph of renal medulla after shock from intestinal obstruction plus surgical intervention. Hyaline and pigmented casts, erythrocytes within the lumens and desquamation of the lining are shown (Army Medical Museum, negative 86830).

It is commonly known that severe infections of various types often disturb renal function. This seems to depend on the severity rather than on the species of the infection. Numerous accounts of febrile albuminuria may be found; only occasionally did the authors of such articles recognize a relationship to shock. The following is an instance.

CASE 4.—Severe illness developed in this man, with moderate leukocytosis and a temperature of 103 to 104 F. He was treated with sulfonamide drugs and penicillin without effect. The blood pressure declined to 80 systolic and 60 diastolic. He became anuric, and uremic crystals covered the cutaneous surfaces. The nonprotein nitrogen rose to 288 mg. and the creatinine to 6.6 mg. per hundred cubic centimeters of blood, on the eleventh day of illness. He died in coma on the twelfth day. From the character of the illness and the postmortem observations a provisional diagnosis of systemic tularemia was made.

The necropsy revealed numerous scattered nodules in the lungs and spleen. These contained necrotic areas, fibrin and monocytic infiltration such as occur in tularemic inflammation. The spleen and liver were enlarged, the viscera were hyperemic. The kidneys were moderately swollen and contained capillary hemorrhages. There was extensive degeneration and necrosis, especially severe in the proximal portion of the convoluted tubules. The lumens contained débris and casts, both hyaline and granular. These features were of the same order as those seen in renal deficiency from other causes.

It is well known that either hyperthermia or heat stroke may cause circulatory collapse; in some instances the subject may survive several days in a state of sublethal shock accompanied by renal deficiency. The following case reports are instances.

CASE 5.—Circulatory collapse developed in this man after six hours at 107 F. in hyperthermic treatment for gonorrhea. On his removal from the cabinet the blood pressure fell to 50 systolic and 30 diastolic. The pulse rate was 156, and the urea nitrogen of the blood was 22 mg. per hundred cubic centimeters. There were oliguria and albuminuria, and the urine contained erythrocytes and casts. Supportive treatment was inffective, the circulatory deficiency continued and the blood urea nitrogen level rose to 77 mg. per hundred cubic centimeters. Death came ninety-eight hours after the therapeutic hyperthermia.

As is usual in such cases, the visceral findings were those characteristic of secondary shock. The kidneys, weighing 240 and 250 Gm., were swollen and reddish brown. The cortical markings were obscure, and the pelvic lining contained petechial hemorrhages. Microscopically, both cortex and medulla were hyperemic. The tubular epithelium was severely degenerated; the lumens were wide and contained débris and desquamated cells; the collecting tubules contained casts and many erythrocytes. The stroma was edematous.

CASE 6.—In this man there developed nausea, vomiting, weakness and circulatory deficiency while he was working in excessive heat. Other observations were a rapid pulse rate, low blood pressure and hemoconcentration. The following day the urine was scanty; it contained albumin, red cells and casts. The circulatory deficiency continued despite the administration of plasma and saline fluids intravenously. The blood urea level rose progressively, and death occurred six days after the collapse. Clinically this case was designated as heat exhaustion. Pronounced visceral hyperemia, serous effusions, edema, petechial hemorrhages and severe parenchymatous degeneration were revealed at necropsy. The renal observations were similar to those in the preceding case, except that tubular necrosis was more advanced and there were more casts in the lumens.

In military aviation at high altitudes circulatory collapse resembling surgical shock often developed even though oxygen was adequately supplied. "The most dangerous aspects are seen after a latent period of one to six hours, resulting in a full-blown vicious circle of peripheral circulatory insufficiency, tissue anoxia and marked hemoconcentration."[13] I had the opportunity to examine the records and material in 5 such cases. The following is a typical example.

CASE 7.—This man was undergoing a test in the low pressure chamber at a relative altitude of 38,000 feet when pains and distress developed. After gradual recompression he seemed drowsy and incoherent, and he was put to bed immediately. The pulse rate then was 80, and the blood pressure, 110 systolic and 80 diastolic. Severe circulatory deficiency developed four hours later; the pulse could not be obtained, the hematocrit reading had risen to 64.9, the patient was sweating and apparently was in profound shock. He was given plasma and isotonic solution of sodium chloride intravenously and oxygen by inhalation. Severe hyperpyrexia developed like that which accompanies heat stroke; the rectal temperature rose to 108.4 F. The urine was scanty and contained albumin 4 plus. No blood chemical tests were made. Despite the administration of intravenous fluids and other measures the circulatory deficiency persisted; death came forty-five hours after the patient's removal from the low pressure chamber.

---

[13] Physiology of Flight, Air Forces Manual 25-2, United States War Department, Army Air Forces, 1945, pp. 17 and 36.

The necropsy observations were the same as those seen in secondary shock from other causes. Microscopic examination of the kidneys revealed the identical pattern of changes seen in the crush syndrome or after transfusion with incompatible blood. It is highly significant that numerous pigmented casts were found, although no transfusions and no therapy with sulfonamide compounds or other drugs had been given.

Space is lacking for details of other instances. These would include intestinal obstruction, peritonitis, perforations of viscera, coronary occlusion, radiation sickness, toxic jaundice, transfusion reaction, anaphylaxis, poisoning with various chemicals, reaction to arsenical therapy, overdoses of sedatives and of sulfonamide drugs, diabetic crises and others. Each of these conditions, if its severity is maximal, will result in the syndrome of shock leading to death. Each of them, when less severe, may cause the syndrome of uremia leading to delayed death. The morphologic changes in the kidneys are of the same pattern, regardless of the causative condition.

Several factors may operate to cause degeneration and necrosis of the tubular epithelium. Poisons, as mercury, arsenic and others, are believed to damage the cells directly. Toxins and other products of bacterial metabolism may have a similar action. Many believe that toxic factors are concerned in shock from trauma or burns. In open contaminated wounds bacterial metabolic agents are an additional factor. Bile and other metabolic agents in abnormal concentration may be injurious to parenchymatous cells. Hence, in cases of poisoning, infections, contaminated wounds and metabolic intoxications, it is possible that the agents mentioned may be responsible for the cellular damage. However, exactly the same pattern of degenerative changes develop in shock from anaphylaxis, transfusion with incompatible blood, asphyxia and anoxia of various types, coronary occlusion, heat stroke and low atmospheric pressure. The effects in these conditions cannot be explained satisfactorily as due to toxic agents. One concludes that other factors, such as neural influences or anoxia play an important role. The degeneration and necrosis of tubular epithelium probably do not result from a single cause but from several causes which operate in varying combinations.

Because of the diverse conditions of its development, the frequency of this renal disorder is high. My observations confirm those of Jeghers and Bakst[12] that "azotemia is much more commonly due to the mechanisms discussed than to organic renal disease." The patient may die of circulatory or renal failure or from their combined effects. When he survives for a time, the oliguria may suddenly give place to polyuria. This is regarded as a favorable sign, indicative of the return of renal function and the beginning of convalescence. When recovery occurs the tubular epithelium regenerates and there are no residual alterations, either morphologic or functional, in the kidneys.

Several explanations have been proposed for renal deficiency associated with sublethal shock. It has been suggested that glomerular filtration, which depends partly on capillary blood pressure, is decreased because of the low arterial pressure which accompanies shock. Reduced filtration would reduce renal elimination correspondingly. However, the blood pressure is not regularly below normal; this syndrome frequently develops even though the blood pressure is maintained at adequate levels by intravenous therapy.

Again, it has been suggested that the glomeruli are unable to produce a filtrate from blood which is above normal concentration. This factor may be of importance when hemoconcentration is pronounced. However, renal insufficiency is present often in the absence of hemoconcentration; in many cases reported, uremia was severe but the blood was not concentrated.

Several have suggested that the deficient excretion of urine is due to mechanical blockage of the tubules by plugs of débris. If this were the chief factor in reducing renal elimination, the kidneys should be swollen beyond the maximum size recorded in any such cases. Also, I have never seen an instance in which as many as 20 per cent of the tubules were obstructed by casts. The *remaining* 80 per cent of unobstructed tubules should be adequate to maintain renal elimination within physiologic limits.

Richards'[14] investigations on renal function provide an acceptable explanation for renal deficiency associated with damage to the tubular epithelium. They showed that degeneration of the epithelium reduced its function of selective absorption, by which the glomerular filtrate is concentrated during its passage through the convoluted tubules. When these were seriously damaged they allowed the entire filtrate to be resorbed into the circulation by a process of diffusion. This produced decided oliguria or anuria by the interruption of renal secretion. Without attempting a final explanation for renal functional deficiency associated with shock, I lean toward the interpretation suggested by Richards.

This form of renal disease is not new; it was described by internists fifty years ago under such terms as acute nephritis, acute Bright's disease and acute parenchymatous nephritis. Osler[15] cited poisoning with various chemicals and drugs, diphtheria, influenza and other severe infections, surgical operations, trauma and burns among the conditions of its occurrence. The clinical signs included oliguria, albuminuria, hematuria, casts, dark or smoky urine having a high specific gravity and uremia.

Pathologists contemporary with Osler (Ziegler,[16] Kaufmann,[17] Coplin,[18] Adami,[19] Delafield and Prudden[20]) described the chief morphologic features, as given in a preceding paragraph, under such terms as acute tubular nephritis, acute parenchymatous nephritis, desquamative or degenerative nephritis and acute Bright's disease. The conditions of its occurrence were those given by the internists. Both Adami and Ziegler stated that it may be impossible to distinguish between cloudy swelling and this form of nephritis.

When the present terminology of renal disease was proposed, acute parenchymatous nephritis or tubular disease had been dropped from the list; hence both clinicians and pathologists have lost sight of its importance. This terminology is deficient in that it provides no name for this entity. Such terms as acute tubular disease, tubular nephrosis or toxic nephrosis would indicate this condition adequately.

SUMMARY

Oliguria or anuria occurs regularly during the development of secondary shock. Deficiency of renal function becomes a prominent feature if a state of sublethal shock persists for a time.

This deficiency is manifested clinically by oliguria, albuminuria, hematuria, casts and the progressive retention of nitrogenous wastes often terminating in uremia.

The pathologic renal features include hyperemia and edema, parenchymatous degeneration ranging to necrosis of the tubular epithelium, desquamation of the lining, débris, and hyaline, granular and sometimes pigmented casts in the lumens.

These changes may result from toxic or from anoxic effect on the renal epithelium. This form of renal disorder is of common occurrence because of the various conditions which may cause shock. If the causative condition is abated, recovery may follow In such cases the cells regenerate and no permanent structural changes result.

This renal disorder formerly was known to pathologists and clinicians as acute parenchymatous, desquamative or acute tubular nephritis. It is not discussed adequately in recent medical treatises.

THE RENAL LESIONS IN EXTENSIVE CUTANEOUS BURNS

P. C MARTINEAU, M D
and
F. W. HARTMAN, M D
Detroit

The literature dealing with the pathologic anatomy of the kidneys following severe cutaneous burns is extensive. Descriptions of the gross lesions were published by Cumin[1] in 1823 and by Long[2] in 1840, but these are chiefly of historical interest The modern concept of the renal changes associated with burns began with Wertheim's[3] description in 1867 of his findings in dogs, supplemented in 1868 by study of a severely burned patient. Utilizing the observations of Schultze[4] (1865) on the degenerative changes in red blood cells on a heated *microscopic stage*, Wertheim described crystals of blood pigment in the renal tubules in both his experimental animals and patients. The parenchymatous changes he referred to as a form of "Bright's kidney."

The presence of hemoglobin in the renal tubules after severe burns was confirmed by Ponfick[5] (1876), Fraenkel[6] (1889) and others. Ponfick also described "intensive congestion of the larger renal arteries, vasa afferentia and glomerular loops, with red blood cells, as well as a moderate, fatty infiltration and hyaline casts in the convoluted tubules." Fraenkel suggested that the plugging of the renal tubules with blood pigment might be responsible for the oliguria and renal changes in the presence of serious burns.

Welti[7] (1889) found scattered hyaline and granular thrombi in the arteriolae rectae and other renal vessels of rabbits burned with hot water. Similar thrombi were produced experimentally by Silbermann[8] (1890) and were recorded in human necropsies by Bardeen[9] (1897), Weiskotten[10] (1919), Vogt[11] (1929) and others.

Inflammatory changes in the tubules of the cortex, with the formation of an exudate, were demonstrated by Schjerning[12] (1884). Wilms[13] (1901) and Marchand[14] (1908), however, denied the existence of a *nephritis due to burns, though they* both noted the degenerative changes in the tubules reported by earlier workers; and Marchand asserted, in agreement with Wertheim, that these changes were due to the excretion of hemoglobin. Dohrn[15] (1901) was able to find pathologic lesions of the kidneys attributable to burns in only 3 of 9 necropsies which he reported.

In a study of the internal lesions of patients dying of superficial burns, McCrae[16] (1901) noted an endothelial hyperplasia in the glomerular capillaries. In 3 cases recorded by Raysky[17] (1910) the alterations in the kidneys were of varying intensity. In 1 only slight changes in the glomeruli were present, while in another there was a diffuse necrosis. In the remaining case, which was intermediate between the others in severity, there was an infiltration of round cells, "chiefly localized about the glomeruli," but without glomerular destruction. Heyde and Vogt[18] (1913) observed an accumulation of lipoids in the interstitial tissues of the kidneys, and Zinck[19] (1938) found a high grade edema in the large renal vessels and calcium deposits in the tubular epithelium.

Moon and Kennedy[20] (1932), studying the shock syndrome, demonstrated "dilatation and engorgement of the capillaries and venules," including those of the kidneys and lungs, and increased "permeability of the capillary walls, as indicated by petechial hemorrhages and effusion into serous cavities." In his subsequent extensive work on the pathologic anatomy of shock,

Moon indicated the many points of similarity between "burn shock" and shock due to other causes.

In 2 patients who died five hours and five days, respectively, after extensive burns, Davis[21] (1940) found a "congestive hemorrhagic and edematous visceral appearance," which he interpreted as typical of the shock syndrome. Olson and his co-workers[22] (1944), however, were able to differentiate between burn shock and tourniquet and hemorrhagic shock in dogs on the basis of the renal output following infusions of saline solution. In the unburned animals renal output was increased by the infusion, but no such change was observed in those suffering from shock incident to burns.

The most extensive clinicopathologic correlations in cases of burns are those of Christophe[23] (1939). On the basis of detailed clinical and autopsy records of 164 burned dogs he postulated the presence of an "acute glomerulonephritis" characterized clinically by: (1) oliguria with albuminuria and casts, or anuria, for twenty-four to forty-eight hours; (2) progressive rise in the nonprotein nitrogen and blood urea nitrogen; (3) lowering of plasma osmotic pressure and reversal of the albumin-globulin ratio; (4) decrease in total blood volume; (5) decreased alkaline reserve and p_H of the blood; (6) decreased plasma chlorides, and (7) increased blood cholesterol. The renal lesions were described by Christophe as identical with those of "acute glomerulonephritis," consisting in extensive glomerular congestion and tubular degeneration. He asserted that there is a toxic principle in the blood returning from the burned area; that in the first ten hours after the burn this principle is absorbed, and that to it, and secondarily to its effect on the brain, the visceral lesions are due.

TABLE 1.—*Summary of Renal Changes Associated with Extensive Burns*

I. Exclusively early changes (first 72 hours): hemoglobin casts in the tubules, bilateral cortical necrosis

II. Exclusively late changes (after 72 hours): acute interstitial nephritis, metastatic abscesses

III. Changes seen both early and late:

1. Degenerative changes in the tubules
    - (*a*) Albuminous degeneration, vacuolar degeneration, and simple necrosis, particularly of the proximal convoluted tubule, and Henle's loop, less frequently of the distal convoluted tubules
    - (*b*) Degenerative fatty infiltration of the tubules
2. Congestion of the blood vessels with erythrocytes
3. Interstitial and submucosal hemorrhages
4. Thrombi: hyaline in the glomerular loops, granular in the larger vessels
5. Infarcts: hemorrhagic and anemic
6. Glomerular endothelial hyperplasia
7. Hyaline, granular and hemoglobin casts
8. Interstitial edema

This recapitulation is based on the observations of previous investigators.

A similar attempt to correlate the clinical and pathologic data was made by Goodpastor and his associates[24] (1946) in 47 patients with severe thermal burns, some of them victims of the Cocoanut Grove disaster of 1942. In 20 patients definite morphologic changes in the kidneys were demonstrated at necropsy. In addition to necrosis and the presence of pigment and cellular casts in the tubules, these writers reported in some instances a regeneration of the tubular epithelium, which they interpreted as "indicative of repair of tubular necrosis."

Brown and Crane[25] (1943) reported a case of bilateral cortical necrosis of the kidneys in a woman who died the sixth day after receiving severe burns involving 40 per cent of the body surface. The renal vascular damage in this case—probably the most extensive to be recorded in the literature—apparently coincided with the period of deep shock, the first forty-eight hours after the burn occurred.

Bell[26] (1946) described a vacuolar degeneration of the epithelium of the proximal convoluted tubules. Other important contributors to the literature on the renal pathology in burns include Simonart[27] (1937); Wilson, MacGregor and Stewart[28] (1938); Erb and associates[29] (1943); Baker[30] (1945); Gibson[31] (1945); Pack[32] (1926), and Shen, Ham and Fleming[33] (1943).

A brief recapitulation of the essential findings of previous workers on the renal changes associated with extensive burns is presented in table 1.

OBSERVATIONS ON CURRENT STUDIES

The present report is based on a study of 84 experimentally burned dogs and 20 cases in man. The experimental observations were made at the Henry Ford Hospital on a series of animals which has served as a basis of previous papers on other aspects of thermal burns (Hartman,[34] 1941, 1943 and 1946). Data on 14 of the human cases were obtained from the autopsy files of the Department of Pathology of the University of Michigan, while data on the other 6 came from the Henry Ford Hospital.

On the trunks of dogs previously anesthetized with morphine and chloroform, second and third degree burns were inflicted by steam jet in 12 instances and by Bunsen burner in 72. The burns were of uniform depth and extent, comprising about 60 per cent of the body surface. The animals were kept under morphine sedation, and dressings of various types (tannic acid, tannic acid-silver nitrate, ferric chloride, boric acid ointment and petrolatum) were continuously applied. As these dressings appeared to have no influence on the renal changes, further reference will not be made to them. In a few instances treatment with penicillin was given; although this seemed to retard infection and thus prolonged life; it was apparently without effect on the pathologic process. The dogs were observed until death, and autopsies were performed immediately. A few moribund animals were killed.

The renal observations in the animals and the human beings are summarized in table 2.

Vascular Congestion; Hemorrhages; Infarcts; Pyelonephritis.—Congestion of the renal vessels was present in at least 70 per cent of the human material and 75 per cent of the experimental animals. It was found to be greatest in the outer medulla and cortex and to involve chiefly the capillaries and venules.

Hemorrhage was not frequently observed. When it occurred independent of infarcts, it was usually in the outer zone of the medulla. Here, according to von Mollendorff[35] (1930), there are groups of fifteen to thirty small blood vessels (capillaries, arterioles, venules), and it is about these congested vessels that hemorrhages were most commonly seen, though they occurred also in the loose connective tissue beneath the pelvic mucosa.

TABLE 2.—*Renal Observations in Extensive Cutaneous Burns*

	20 Cases in Human Beings			84 Cases in Dogs		
	Present	Doubtful	Absent	Present	Doubtful	Absent
Venous and capillary congestion	14	5	1	63	9	12
Albuminous degeneration and simple necrosis of the proximal convoluted tubule	18	1	1	66	5	13
Albuminous degeneration and simple necrosis of Henle's loop	14	2	4	45	2	37
Vacuolar and necrotic changes of the collecting tubules	3	0	17	25	1	58
Necrosis and débris in Bowman's capsule	7	0	13	25	3	56
Glomerular endothelial hyperplasia	3	3	14	17	1	66
Acute interstitial nephritis	1		19	34		50
Pyelonephritis	3		17	8		76
Infarcts	3		17	8		76
Hemorrhages	4		16	13		71
Casts	7		13	9		75

Glomerular congestion was of much the same degree as that in the capillaries except in the presence of small contracted glomeruli or glomerular endothelial hyperplasia.

No hyaline or granular thrombi, such as those produced experimentally by Welti (1889), Silbermann (1890) and Simonart (1937) were seen in our materials. A possible explanation for this lies in the duration of the burning. Their animals were burned for much longer periods than ours, and it may be that the prolonged heat bears a direct relation to the production of thrombi. Septic bacterial emboli were present in 8 of our dogs and 3 of the human cases, with resultant hemorrhagic infarcts and pyelonephritis.

Albuminous Degeneration.—The albuminous degeneration and simple necrosis of the proximal convoluted tubules and of the ascending thick segments of Henle's loop did not differ from these changes as described by others, from Ponfick (1876) to the present day.

Presumptive evidence of regeneration of the tubular epithelium was seen in 29 of the 79 dogs that lived more than two days after burning. Such evidence consisted in (*a*) the presence of necrosis of the tubular epithelium, usually manifested by coarse eosinophilic debris in the lumen, without the formation of casts, and (*b*) new, well-defined low tubular epithelial cells with normal staining qualities. No mitotic figures such as those described by Goodpastor and his associates[24] (1946) and shown in their photomicrographs were encountered. While we have accepted the criteria previously noted as presumptive evidence of regeneration, we realize that they constitute only a doubtful basis for such an assumption. In the proximal convoluted tubules the medial border of the epithelium is sharply defined, and neither the brush border of the normal cell nor the frayed-out border of the necrotic cell is seen. It is extremely difficult, if not impossible,

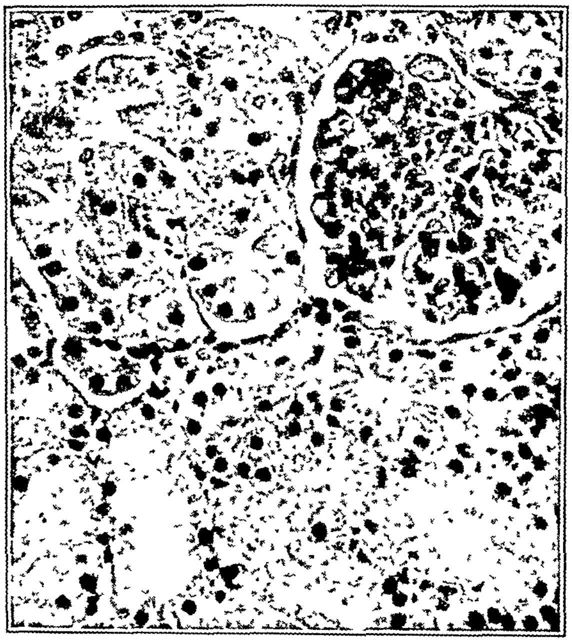

Fig 1 (case 3).—Photomicrograph of renal cortex (medium power). The survival time was twelve hours Note the albuminous degeneration and necrosis of the proximal convoluted tubules in contrast to the glomeruli, which appear normal

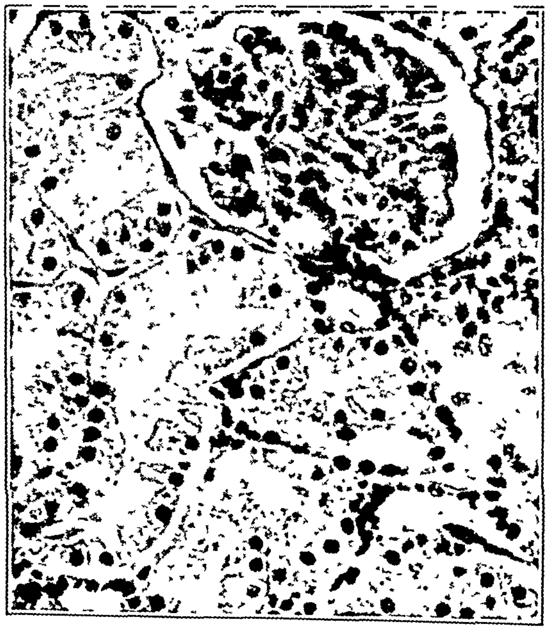

Fig 2 (case 3).—Photomicrograph of renal cortex (medium power). Note the albuminous degeneration and necrosis of proximal convoluted tubules

to distinguish a regenerated epithelial cell from epithelial cells that have simply survived the early phases of the burn. Tilp[36] (1925), who has written extensively on "intracanalicular regeneration" of tubular epithelium, has stated that the process is characterized by the appearance of mitotic figures, the presence of new epithelium and the appearance of epithelial multinucleate giant cells.

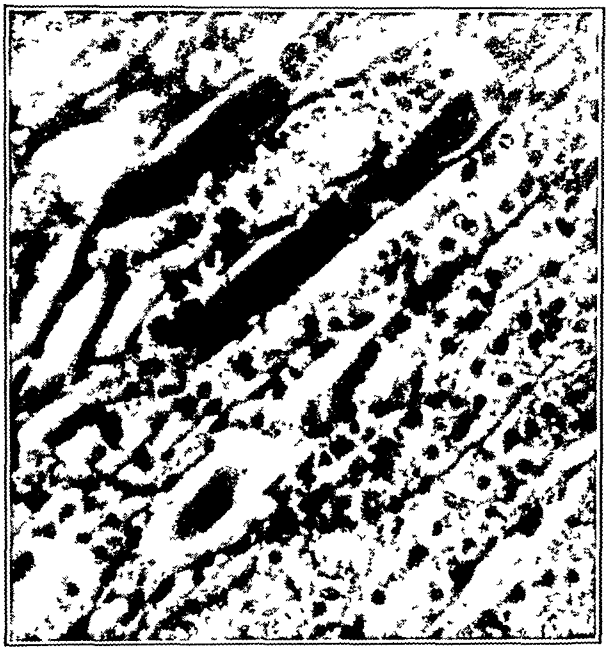

Fig 3—Photomicrograph of the medulla (inner zone) of the kidney of dog 3280 (medium power). The survival time was eleven days Note the hyaline casts and the vacuolar changes in the collecting tubules

Vacuolar and Necrotic Changes in the Tubules—Vacuolar degenerative changes in the proximal convoluted tubules were seen in 3 of the dogs but were not present in any of the human cases In no instance were they of the extreme degree shown by Bell[26] (1946) in his photomicrographs. The vacuolar and necrotic changes in the collecting tubules were principally confined to the medullary rays in the cortex. The vacuoles were of various sizes. Many filled the entire cytoplasmic portion of the cell. In such cells the nuclei were pyknotic. The cell borders were strikingly clear as prominent eosinophilic lines. The cytoplasm, however, was so modified that only a small amount of eosinophilic dust was seen in the large vacuoles. In the areas of milder change the cells had the appearance of hydropic degeneration, in other areas they appeared necrotic. These vacuolar and necrotic changes in the collecting tubules were found in 25 animals, 18 of which were in the first nine day survival group.

Similar changes were recorded in 3 of the human cases. The cause of this vacuolar change is obscure, but similar necrotic changes have been produced in the proximal convoluted tubules of rabbits by repeated injections of sucrose and dextrose (Helmholtz,[37] 1933). It is of interest that in 1 instance (case 10), that of a child aged 2½ years who showed hydropic degeneraion of the proximal convoluted tubules at necropsy, 100 cc. of a 25 per cent solution of dextrose had been administered two hours before death.

Necrosis and Débris in Bowman's Capsules Casts—Many of the degenerating tubules and capsules of Bowman were observed to contain eosinophilic amorphous débris, but true casts were infrequent. Three patients who died within seventy-two hours after receiving their burns showed casts of erythrocytic débris. Hyaline casts were also infrequent, being observed in only 9 dogs and 7 human cases. A few fresh eosinophilic hyaline casts were noted in distended collecting tubules, and in 1 instance numerous older, partially calcified, hyaline casts were present in undistended tubules. This was the only evidence of calcification in the kidney which was encountered in our study. Extensive calcification of the renal tubules after burns was reported by Zinck[10] (1938) and attributed by him to hypochloremia.

Fatty Infiltration.—Degenerative fatty infiltration of the kidney was noted in 6 of 14 autopsies in which fat stains were used. The small round orange globules of fat, stained with sudan III, were just visible at the base of the tubular epithelial cells. In some of these cases there was an associated fatty degenerative infiltration of the heart and liver. This change was considered to be due to the same factors as those which produce albuminous degeneration and simple necrosis, i. e, anoxia and metabolic poisons. In some of the cases reported here the process was so mild as to appear reversible.

Glomerular Endothelial Hyperplasia.—Glomerular endothelial proliferation was infrequent and, except in a few cases of old infected burns, was of a minimal and even questionable nature. In no case was the endothelial proliferation great enough to occlude the capillary lumens. Necrotic changes were also infrequent and, when they did occur, were usually attributable to embolic infections and postmortem change. We agree

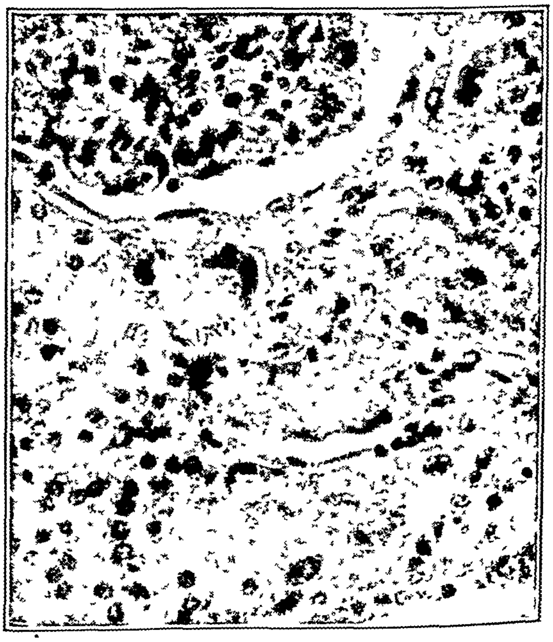

Fig 5 (case 8)—Photomicrograph of renal cortex (medium power) The survival time was forty six hours Different degrees of necrosis are shown in the proximal convoluted tubules Note the complete necrosis of the proximal convoluted tubules in contrast to the well preserved nature of the malpighian corpuscle

with Wilms, Marchand, Vogt and others that there is no acute glomerulitis due to burns. This point, however, argues neither for nor against a circulating burn toxin.

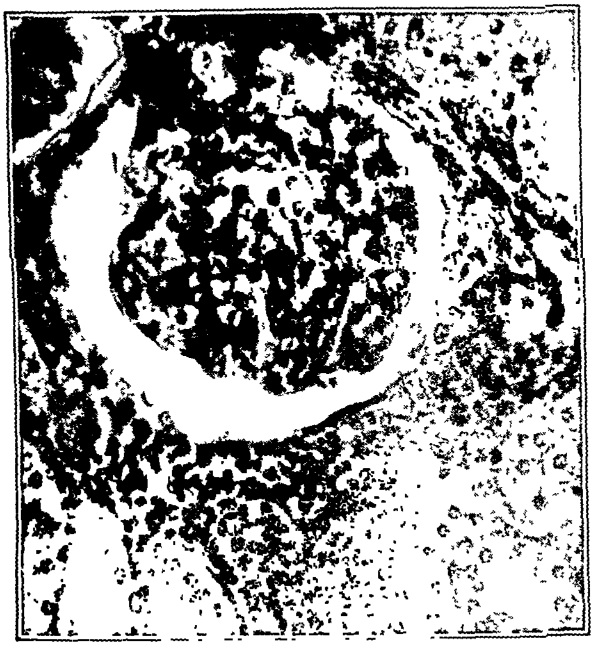

Fig 8—Photomicrograph of renal cortex of dog 3096 (medium power) The survival time was ten days Note the lymphocytic infiltration about the parietal wall of Bowman's capsule.

Acute Interstitial Nephritis.—In 34 of our dogs and in 1 of our human patients (case 17) an acute interstitial nephritis was observed. In an apparently similar case reported by Raysky (1910) the patient died three days after being burned. In no instance in our experience was acute interstitial nephritis seen before the third day, and in no case did it occur in the absence of secondary infection of the kidney. Classic descriptions of acute interstitial nephritis have been published by Councilman[38] (1897), Reichel[39] (1905), Marchand[40] (1913) and Aschoff[41] (1913). Our cases showed numerous foci of lymphocytic and plasma-cell infiltration in the lymph spaces and in the interstitial spaces immediately adjacent to the capsules of Bowman and the small blood vessels. The cortex was predominantly involved, but there were areas of infiltration also in the loose connective tissue about the larger vessels and beneath the pelvic mucosa. Seldom did the foci of infiltration surround the entire capsule of Bowman; when they did, the adjacent capsular epithelium became swollen and necrotic. In some such areas the glomerular loops were also contracted and degenerating. In general, in the immediate vicinity of small foci of infiltration the tubules were not altered in appearance, but in the more extensive foci of infiltration the tubules were replaced by infiltrating cells. The foci often followed the medullary rays through the cortex as prominent dark blue streaks. It is not known whether the lymphocytes come from the lymphoid structures in and about the kidney or from the blood. In the opinion of Fahr[42] (1925) they represent a response by the patient to the presence of a powerful bacterial exotoxin, such as those formed in diphtheria, scarlet fever and certain wound infections. The data in our cases suggest the presence of such an exotoxin associated with secondary infection of the burn areas. Fahr stated that kidneys showing such lymphocytic infiltration might return to normal with perhaps some scarring.

COMMENT

In summary, the most important pathologic lesions in the kidneys following extensive burns in the animal and human series here reported were found to be: (1) degenerative changes in the tubules; (2) congestion of the capillaries and venules; (3) tubular casts of the products of intravascular hemolysis, and (4) lesions due to infection.

The two principal pathologic-physiologic mechanisms which are believed to cause this damage are: shock and intravascular hemolysis. The significance of shock is twofold: Prolonged shock produces irreversible tubular degeneration and causes extrarenal uremia. With a fall of systolic blood pressure of 50 per cent, the volume of blood circulating through the kidney may be reduced 95 per cent, according to Richards[43] (1944). The result is oliguria or anuria with extrarenal azotemia.

The significance of intravascular hemolysis is less well understood. Earlier writers reported hematuria in a small minority of burn cases. Goodpastor (1946) found hemoglobinemia in all of his 20 patients with renal lesions and in all but 6 of the remaining 27 without pathologic changes in the kidneys. The frequency of intravascular hemolysis in the presence of extensive cutaneous burns is strikingly demonstrated by these figures.

Monke and Yuile[44] (1940) showed in experimental studies on dogs that the excretion of hemoglobin has a true renal threshold—about 100 mg. per hundred cubic centimeters—above which it is eliminated by the kidney at a rate directly proportional to its concentration in the plasma. They offered considerable evidence to show that, below this level, the hemoglobin in the glomerular filtrate is completely absorbed by the renal tubules, without injury. Recently Yuile, Gold, and Hinds[45] (1945) have reviewed the literature on the toxicity of the products of hemolysis on the kidney and, on the basis of their experimental material, have asserted that precipitation of hemoglobin in the renal tubules, and hence renal tubular necrosis, is primarily dependent on antecedent damage to the tubules and not on the acidity or alkalinity of the urine or the amount of hemoglobin in the blood. This antecedent damage to the kidneys may be produced by ischemia, shock or chemical poisoning. It is etiologically nonspecific.

Others have speculated on the possibility of a more toxic product of intravascular hemolysis, from either the erythrocyte stroma or a derivative of hemoglobin, as the cause of the extensive tubular necrosis about the hemoglobin casts.

There is a striking similarity between the hematuric "burn" kidney and the renal observations in other conditions characterized by intravascular hemolysis, such as those following incompatible transfusions of blood, in hemolytic reactions to sulfonamide therapy and in malaria. The "crush syndrome" kidney, in which casts of a myohemoglobin are present, exhibits a comparable picture.

Finally, it may be stated that, while the renal lesions following extensive cutaneous burns are usually of a minor, secondary and probably reversible character, with little danger to the patient, there are in a minority of cases more serious lesions caused by prolonged shock or by a combination of shock and intravascular hemolysis, or by infection, which may lead to renal insufficiency, renal destruction and death.

REPORT OF CASES

Abstracts of the 20 human burn cases follow:

Case 1.—A white man aged 37 had second and third degree burns involving 90 per cent of the body surface received from steam in a railroad accident. The survival time was four to five hours; there were multiple fractures and a history of shock. Autopsy observations included: multiple pulmonary fat emboli, severe catarrhal bronchitis with ulceration, aspiration bronchitis, edema of meninges and brain substance and congestion and edema of the lungs. The renal examination showed gross cloudy swelling, mild congestion of the vessels including the glomeruli, severe albuminous degeneration and necrosis of the proximal convoluted tubules and thick ascending portion of Henle's loops, hyaline casts; submucosal hemorrhages in the kidney pelvis, moderately severe postmortem changes and mild degenerative fatty infiltration of the tubules.

Case 2.—A white girl aged 3 years fell into a brush fire. First, second and third degree burns involved over 50 per cent of the body surface. The survival time was seven hours. There was a history of severe shock. Observations at autopsy included: cerebral edema, aspiration of food into the bronchi, pulmonary congestion and edema, patchy emphysema and atelectases, with terminal right-sided cardiac dilatation. The kidneys showed congestion of vessels including glomeruli with red blood cells, decided albuminous degeneration and some necrosis of the proximal convoluted tubules and ascending thick portion of Henle's loop, with vacuolar degeneration of the collecting tubules in the cortex.

Case 3.—A white boy aged 5 had his clothes ignited while he was playing with matches. Second and third degree burns involved the entire trunk from pubis to chin including the neck and arms, with some charring. Sixty to 70 per cent of the body surface was involved. The survival time was twelve hours, with a history of severe shock and hematemesis. The treatment had been débridement and 5 per cent tannic acid spray. Autopsy observations included acute catarrhal bronchitis, pulmonary congestion and edema. The kidneys showed mild congestion of the blood vessels, including the glomeruli, with erythrocytes; there was albuminous degeneration and necrosis of the proximal convoluted tubules.

Case 4.—A Negro woman aged 50 had the anterior surface of the body, comprising 30 per cent of the body surface, burned with steam or hot water. She suffered first and second degree burns. The survival time was less than twenty-four hours; the exact time is not known. There was a history of shock. At autopsy the observations were: right-sided cardiac dilatation with relative tricuspid and pulmonary insufficiency; atrophy, passive congestion and parenchymatous degeneration of all organs; syphilitic aortitis, and lipoidosis of the adrenals. In the kidneys the gross observations were as follows: The capsule stripped with some increased difficulty; the surface was slightly granular. Acute passive congestion, atrophy and one old infarct were seen. Microscopic examination revealed congestion of the vessels and glomeruli. There were albuminous degeneration and necrosis of the proximal convoluted tubules and ascending thick portion of Henle's loops, interstitial edema in the medulla, hyaline casts, sclerosis of the vessels and postmortem changes.

Case 5.—A white woman aged 80, whose clothes ignited while she was smoking in bed, had 75 per cent of the body surface involved in second and third degree burns. The survival time was twenty-four hours. Treatment consisted in petrolatum gauze and pressure bandages, plasma and fluids for shock. There was a history of oliguria (60 cc. after burn). Autopsy examinations showed acute tracheobronchitis, pulmonary congestion and parenchymatous degeneration of the liver and adrenals The kidneys on gross examination showed atrophy; the capsule stripped with slightly increased difficulty, leaving a finely granular surface; congestion was evident. Microscopic study revealed some congestion of the arterioles, capillaries and small veins but not of the glomeruli; also evident were glomerular endothelial hyperplasia, interstitial edema of the medulla, albuminous degeneration of the proximal convoluted tubules and thick ascending portions of Henle's loop and sclerosis of the vessels.

Case 6.—A white girl aged 3 years suffered second and third degree burns from the explosion of a gasoline stove, with 25 per cent of the body surface burned. The survival time was twenty-eight hours. A history of "toxic encephalitis" and terminal bilateral pneumonia was recorded. Autopsy observations were: acute passive congestion of all organs, petechial hemorrhages in the lungs, moderate parenchymatous degeneration of heart, liver and kidneys, acute catarrhal gastroenteritis and congestion and edema of the brain. The kidneys on gross examination showed severely congested, ground-glass appearance on cut section. Microscopic study disclosed congestion of the vessels and glomeruli with erythrocytes, albuminous degeneration of the tubules and ascending thick portion of Henle's loops, slight generalized glomerular endothelial hyperplasia, no lipoidosis and some foci of round cell infiltration.

Case 7.—A Mexican girl 2 years of age fell into a tub of scalding water. There were second and third degree burns over 35 per cent of the body surface. The survival time was forty hours. Tannic acid spray, 5 per cent, and blood transfusions were included in the treatment. There was a history of convulsions and pulmonary edema. At autopsy there was seen dehydration of all tissues with anhydremia, acute parenchymatous degeneration of the liver with beginning fatty metamorphosis, hemorrhage into the right adrenal gland and lymphadenopathy of the mesenteric glands. The kidneys on gross examination showed extreme congestion. Microscopic study disclosed congestion of the vessels with erythrocytes, albuminous degeneration of the proximal convoluted tubules and ascending thick portion of Henle's loops. There was some postmortem change.

Case 8.—A white man aged 38 was burned in an automobile accident. He had first, second and third degree burns involving 40 per cent of the body surface. The survival time was forty-six hours. He was treated with tannic acid and there was a history of shock and anuria. At autopsy the observations were: generalized edema, gangrene of the ileocecal region and sigmoid with thrombosis of the mesenteric veins and hemorrhage into the gastrointestinal tract, localized fibrinopurulent peritonitis, acute purulent bronchitis and lobar pneumonia, thrombi in the pulmonary arterioles, severe esophagitis and a small infected infarct of the adrenal. The gross renal examination showed some edema. Microscopic study of the kidneys revealed congestion of the vessels and glomeruli, petechial hemorrhages beneath the pelvic mucosa and in the medulla, casts of erythrocytic débris in the collecting tubules, albuminous degeneration and simple necrosis of the epithelium of the proximal convoluted tubules and ascending thick portion of Henle's loops. Abundant protein débris was present in the tubules; there was a slight arteriolosclerotic nephropathy, with mild fatty infiltration of the collecting tubules.

Case 9.—A white girl aged 6 years, whose clothes caught fire from a gas stove, had 45 per cent of the body surface involved in first, second and third degree burns. The survival time was forty-eight hours. Treatment included débridement, 7 per cent tannic acid jelly, adrenal cortical extract and blood transfusions. The history told of pulmonary edema and oliguria, prolonged and repeated emesis. There was a coroner's autopsy. Sections of heart, lungs, spleen, kidneys and liver were returned to Henry Ford Hospital. Autopsy observations were: edema and congestion of the lungs and myocardial degeneration. The kidneys exhibited mild congestion of the vessels but not of glomeruli, albuminous degeneration and simple necrosis of the proximal convoluted tubules and the ascending thick portion of Henle's loop. There were casts of erythrocytic débris in the collecting tubules.

Case 10.—A white girl aged 2½ years sat in a bucket of hot water. She suffered first and second degree burns which involved 50 per cent of the body surface The survival time was seventy-five hours. The burns were treated with tannic acid jelly and the child received repeated transfusions of blood. There was a history of prolonged stupor, acidosis and rapidly progressive anemia. Autopsy observations included: multiple petechial hemorrhages in the subperitoneal connective tissue, mesentery, omentum and gastrointestinal tract and beneath the visceral pleura; there was hemorrhage into the gastrointestinal tract; generalized edema was present with 400 cc. of ascitic fluid and 100 cc. of pleural fluid in each pleural cavity; decided parenchymatous degeneration of the liver had taken place; pulmonary congestion and hemorrhage were evident. The kidneys on gross examination exhibited several small hemorrhages in the peripelvic tissue and along the left ureter. The microscopic study showed widespread severe hydropic degeneration of the proximal convoluted tubules. ("Patient expired shortly after receiving 100 cc. of 25 per cent glucose" and 100 cc. of blood.) There was mild congestion of the vessels but not of the glomeruli. Erythrocytic débris was seen in the collecting tubules.

Case 11.—A white boy aged 2½ years died two days after extensive second degree burns involving the abdomen, axilla, back, buttocks, genitalia and lower extremities. There was a history of pulmonary edema and symptoms of toxicity. The autopsy showed: acute purulent bronchitis and fibrinopurulent lobar pneumonia; severe pulmonary congestion; edema and hemorrhage; patchy emphysema and atelectasis; lipoidosis of the myocardium, liver, adrenal cortex and kidneys, and intense acute passive congestion and edema of all viscera. The kidneys showed gross evidence of congestion and cloudy swelling. The microscopic observations were: congestion of vessels and glomeruli, albuminous degeneration and simple necrosis of the proximal convoluted tubules and ascending thick portion of Henle's loop, mild glomerular endothelial hyperplasia and severe degenerative fatty infiltration of the proximal convoluted tubules.

Case 12.—A Negro man aged 36 was burned by spilled molten iron, which ignited his clothes. Second and third degree burns involved 40 per cent of the body surface. The survival time was four days. Treatment consisted in the application of 7 per cent tannic acid jelly and the transfusion of blood. There was a history of bleeding from the gums the day before death. After the coroner's autopsy portions of liver, spleen, kidneys, adrenals and skin were returned to Henry Ford Hospital for sections. The autopsy showed generalized edema, ascites and hydrothorax, myocardial degeneration and extensive passive congestion of the liver, spleen and kidneys. Microscopic study of the kidneys showed congestion of the vessels but not of the glomeruli, albuminous degeneration of the proximal convoluted tubules and ascending thick portions of Henle's loops, necrosis of Bowman's capsule with intracapsular débris and granular casts in the collecting tubules.

Case 13.—A white man aged 24 died four and a half days following first, second and third degree burns involving approximately 30 per cent of the body surface. Autopsy revealed moderate infection and early healing of burned areas; agglutination thrombi in the pulmonary capillaries; cerebral and meningeal edema; a pronounced degree of acute passive congestion of the liver and spleen; patchy interstitial myocarditis; acute catarrhal bronchitis; localized superficial ulceration of the larynx; patchy Zenker's necrosis of the diaphragm, and lymphocytic infiltration of the adrenal gland. The kidneys on gross examination revealed cloudy swelling. The microscopic study disclosed: congestion of the vessels and the glomeruli; albuminous degeneration and simple necrosis of the proximal convoluted tubules, and ascending thick portions of the loop of Henle; recent hemorrhage into the submucosa of the pelvis; no lipoidosis; necrotizing ulceration of the pelvic mucosa, and a basophilic precipitate in some collecting tubules (probably a sulfonamide compound). There was minimal glomerular endothelial hyperplasia.

Case 14.—A white man aged 44 suffered second and third degree burns of the face, neck, hands, feet and right leg when a kerosene can exploded as he was lighting the kitchen stove. A history of secondary infection of burns and septicopyemia was recorded. The survival time was eight days. Autopsy revealed: pyemic abscesses of the lungs, myocardium, kidneys, testes and small intestine; acute fibrinopurulent pericarditis and endocarditis; acute purulent bronchitis and bronchopneumonia; pulmonary congestion, hemorrhage and edema; terminal cardiac dilatation with relative tricuspid and pulmonary insufficiency; acute passive congestion and parenchymatous degeneration of all organs. On gross examination of the kidneys several irregular light-colored areas were seen on the surface. Cut section showed these to be pyramidal, with the base at the periphery. Microscopic study revealed "multiple small embolic abscesses"; many of these contained colonies of cocci. There was albuminous degeneration of the proximal convoluted tubules and ascending thick portion of Henle's loop and congestion of the vessels and glomeruli. Lipoidosis was not observed.

Case 15.—A white woman aged 16 received second and third degree burns from an open furnace door ten days before her death. Autopsy disclosed intense acute passive congestion of the lungs, moderate chronic pulmonary edema and a small hemorrhagic infarct in the lung, with central abscess. Also there was evidence of acute purulent bronchitis, petechial hemorrhages in the submucosa of the bronchioles and congestion of all viscera. The kidneys on microscopic examination exhibited congestion of the vessels and glomeruli, albuminous degeneration and simple necrosis of the proximal convoluted tubules and ascending limb of Henle's loops and minimal glomerular endothelial hyperplasia. There was no lipoidosis.

Case 16.—A white boy aged 18 had his clothes catch fire while he was smoking in bed. There were second and third degree burns of the face, neck, thorax, right arm, abdomen, back, thighs and genitalia. From 60 to 65 per cent of the body surface was involved. The survival time was fourteen days. Autopsy disclosed acute purulent bronchitis and lobar pneumonia, older organizing fibrin in many alveoli and bronchi, bronchiolitis obliterans, pulmonary congestion and extensive hemorrhage, adhesive pleuritis, organizing mural thrombus in the heart, slight degenerative fatty infiltration of the myocardium, edema of the brain and meninges, widespread petechial hemorrhages beneath the serosal surfaces, hemorrhage and necrosis of the urinary bladder and colonic mucosa and submucosa, bone marrow giant cell emboli in the heart and renal glomeruli, shallow acute laryngeal ulcer, small fresh hemorrhagic splenic infarct and hydropericardium. Gross examination of the kidney revealed congestion. Microscopic study showed congestion of the vessels and glomeruli, albuminous degeneration and necrosis of the proximal convoluted tubules with calcification, vacuolar degeneration of Henle's loops and the collecting tubules and small hemorrhages in the medulla. There was no lipoidosis.

Case 17.—A white girl aged 8 years had her clothes catch fire while she was playing with matches. Death resulted fourteen days after extensive first and second degree burns of the neck, thorax, abdomen, back and arms. The treatment included tannic acid dressings. Autopsy revealed cerebral congestion and edema, subepicardial and pulmonary petechial hemorrhages, acute pulmonary edema, patchy atelectasis, degenerative fatty infiltration of the myocardium, liver and kidneys, slight chronic catarrhal tracheobronchitis and shallow acute esophageal ulcers. On gross examination the kidney was softer than usual, with cloudy swelling. Microscopic study revealed congestion of the vessels and glomeruli, lymphocytic infiltration beneath the pelvic mucosa, well advanced fatty degeneration of the tubular epithelium, moderate glomerular endothelial proliferation and acute interstitial nephritis with lymphocytic infiltration about blood vessels.

Case 18.—A white boy aged 3 years died the twenty-fifth day after scalding water caused extensive superficial burns (first, second and third degree) involving the skin of the back, abdomen, thighs, arms and genitalia. There was a history of infection of the burned areas. Autopsy examination disclosed infected burns, pronounced acute passive congestion and parenchymatous degeneration of all viscera, edema of the left foot and the scrotum and emphysema. On cut section of the kidneys a triangular abscess was seen in the upper pole of the left kidney. Microscopic study revealed: albuminous degeneration of the proximal convoluted tubules and ascending thick portion of Henle's loops; congestion of the vessels; areas of recent hemorrhage; early embolic purulent nephritis with several small necrotic foci around small vessels containing infected emboli, and slight degenerative fatty infiltration of the tubular epithelium.

Case 19.—A white boy 10 years of age was splashed with burning oil and 25 per cent of the body surface was involved in second and third degree burns. The survival time was twenty-six days; the burns were treated with tannic acid. Autopsy revealed: acute toxic encephalopathy; severe infection of unhealed burns with pyoderma; acute passive congestion and parenchymatous degeneration of the liver and kidneys; acute ulcerative and purulent esophagitis; agglutination of the red and white cells in the blood stream with multiple small emboli in the meninges and substance of the brain. The kidneys on gross examination were flabby, with cloudy swelling; they were moderately congested and minute yellow granules were adhering to the pelvic mucosa. Microscopic study disclosed congestion of the vessels, albuminous degeneration and simple necrosis of the proximal convoluted tubules, slight degenerative fatty infiltration of the tubules, minimal glomerular endothelial hyperplasia and sulfanilamide casts in the collecting tubules.

Case 20.—A white man aged 38 had gasoline burns of second and third degree, which involved 70 per cent of the body surface. The survival time was twenty-nine days. The burns were secondarily infected. Observations at autopsy were as follows: infected burns; acute chronic adhesive pericarditis; vegetations of the aortic, pulmonary and tricuspid valves; subepicardial fatty infiltration; subendocardial degeneration and fatty infiltration; endocardial sclerosis with fibrosis extending into the myocardium; terminal right-sided and left-sided cardiac dilatation; chronic adhesive and acute fibrinous pleuritis; early acute purulent bronchitis; pulmonary congestion, edema and atelectasis; multiple infarctions in the spleen and kidneys, and passive congestion and parenchymatous degeneration of all the organs. The kidneys on gross examination exhibited a smooth surface with mottled yellow areas in purple-red background; yellow areas were noted in the cortex on cut section. Microscopic study showed multiple infected infarcts, metastatic abscesses, congestion of the tubules and thick ascending portions of the loops of Henle and minimal glomerular endothelial proliferation.

CRUSH SYNDROME: POST-TRAUMATIC ANURIA

Observations on Genesis and Treatment

and
IRVINE H. PAGE, M.D.
Cleveland

Traumatic shock is thought of as an acute state from which no threatening residues persist. As regards recovery of renal function, doubt was cast on this view by reports from the scene of the Messina earthquake and by detailed studies of cases of post-traumatic uremia occurring in the German Army in World War I.[1] Crush syndrome was rediscovered, named and studied on a wider scale during the London blitz.[2] Similar cases have been reported from the accidents of civilian life.[3] Many others, civil and military, have probably gone undiagnosed because fatal shock and sepsis have probably overshadowed the defect of renal function.

Typically, the syndrome is initiated by crush of a limb or occlusion of its arterial supply for several hours. Release from débris or restoration of blood flow is followed by swelling, with whealing at the sites of compression. The limb becomes hard, paralyzed and anesthetic. Loss of plasma into the area of injury causes hemoconcentration. Shock may supervene and be relieved by transfusion. Urine passed during the first twenty-four hours is colored red or brown with myoglobin, contains albumin and shows many brown and black granular pigment casts. Urinary output and specific gravity thereafter diminish. The patient passes into restless delirium with thirst and vomiting. Arterial pressure and concentration of serum potassium are increased. Azotemia rises to about the sixth day, when death suddenly occurs in about two thirds of the cases. The volume of urine of those who are to recover increases about this time, and their renal function is slowly restored in succeeding months.

The anuria which may follow intravascular hemolysis, as by transfusion of incompatible blood, is familiar. Myoglobin, the red pigment of muscle, has the same basic structure as hemoglobin. The fact that its molecule is only a fourth as large permits it to be filtered through glomerular capillaries into renal tubules at about twenty-five times the rate of hemoglobin. Renal failure in crush syndrome was then, by analogy, attributed to deposition of myoglobin casts in the renal tubules.

The exact mechanism of hemoglobinuric nephrosis is not established. There is compelling evidence which associates it with urinary acidity. Renal damage in crush syndrome was therefore attributed to the coincidence of myoglobinuria—due to release of myoglobin from crushed muscle—and aciduria—due to the outpouring of lactic and phosphoric acids from damaged muscle cells.

Others thought it more likely that renal injury in crush syndrome is a consequence of prolonged arterial hypotension with renal ischemia and anoxia; they viewed the blocking of renal tubules with pigment as more a result than a cause of renal damage.

Another view attributes renal injury to toxic substances liberated from injured tissues, either acting directly on renal tubule cells or acting indirectly by decreasing the rate of renal blood flow.

These differences in the point of view are significant, for prevention and treatment of crush syndrome depends on a knowledge of the mechanism which must be countered.

MECHANISM AND TREATMENT OF CRUSH SYNDROME

I. *The Pigment Theory.*—Our experience on the effect of intravenous injection of myoglobin and hemoglobin in normal dogs[4] and in rats with acid urine shows that the renal injury thus produced is highly variable and seldom serious. The renal function most depressed is that of tubular secretion. The degree of impairment is directly proportional to the amount of pigment retained in the kidneys. The amount of pigment retained does not depend directly on urinary p_H within the range 5.0 to 5.8. Rather, renal injury and pigmentary retention seem to depend on the coincidence of aciduria with oliguria (see the accompanying table).

Others[5] have observed renal injury which is occasionally severe in rabbits with acid urine injected with human myoglobin. Our conclusions vary from theirs in that we were unable to cause fatal uremia in normal animals and in our attribution of renal damage to the combination of aciduria with oliguria.

The fact that oliguria as well as aciduria is a requisite of myoglobin renal damage seems to explain some of the divergent reports on the renal effects of hemoglobinuria.[6] Other mechanisms of hemoglobinuric injury have been invoked, as in the suggestion that injection of hemoglobin solutions causes severe renal vasoconstriction.[7] This is not borne out in our experience, for injections of sterile solutions of both myoglobin and hemoglobin and even the initiation of intravascular hemolysis and hemoglobinuria cause no change in renal blood flow. The discrepancy may result from the injection of nonsterile solutions of hemoglobin.

Hemoglobinuric and myoglobinuric renal damage seem largely dependent on the precipitation of pigment casts within the renal tubules. This is most likely to occur when the urine is highly concentrated, i. e., oliguric and acid. These casts injure by causing hydronephrosis of nephrons and groups of nephrons. Pressure from distended nephrons may interfere with the function of some which are still patent. It is not clear that this is the sole mechanism of renal injury from pigment precipitation. Hematin is cytotoxic and when intravenously injected in large amounts causes severe renal as well as hepatic injury.[8] Myoglobin and hemoglobin in acid solution tend to form metamyoglobin and methemoglobin, respectively, and to be precipitated as such. Hematin is easily liberated from these metaforms of the pigments by tissue and urinary enzymes. Part of the renal tubular damage in hemoglobinuria and myoglobinuria may be due to release of hematin from precipitated heme-globin pigments.

II. *Shock, Hypotension and Renal Ischemia.*—Clamping the renal artery for periods of more than an hour results in severe renal structural and functional damage[9] with prolonged ischemia, degeneration largely of the proximal convoluted tubules, azotemia and oliguria, loss of the secretory aspects of renal function and impairment even of the normal selective impermeability of renal tubules. This last injury creates a glomerulovenous circulation of tubular fluid which tends to increase oliguria due to ischemia and may facilitate pigmentary aggregation in the tubules. But clamping of the renal artery reduces renal blood flow to less than 10 per cent of normal. It is not at first apparent that this low level of blood flow can be present in clinically recoverable shock and in the absence of severe hypotension.

Effects on Renal Function of Myoglobin Injection in Rats

Group		Blood Urea Nitrogen, Mg./100 Cc. 24 Hrs. After Injection	48 Hrs. After Injection	72 Hrs. After Injection	No. of Animals in Group
1	Aciduria (p_H 5.2)........	17	17.5	..	16
2	Aciduria (p_H 5.0)........	32	29.0	20	12
3	Aciduria (p_H 5.1) with prior dehydration	58	36.0	28	15

Effect of aciduria alone at two levels of urinary p_H and of aciduria with prior deprivation of water for twenty-four hours in normal rats given 40 mg. of beef metamyoglobin intravenously. Values given for urinary p_H and blood urea nitrogen are means of the observations in each group.

Pertinent to this problem, we have shown that successive periods of prolonged hypotension and early shock due to bleeding result in progressive renal vasoconstriction, such that restoration of arterial pressure and blood volume to normal by transfusion fails to restore renal blood flow to more than 50 per cent of normal.[10] To mimic more closely the conditions of crush syndrome we turned next to studies of renal blood flow and function in dogs to which tourniquets had been applied[11] which all but obliterated arterial inflow to the limbs. Within a few minutes after beginning the experiments, renal blood flow was reduced to 50 per cent of normal, and at the end of an hour it was down to about 20 per cent of normal. Interruption of vasomotor pathways by renal denervation, prevention of hemoconcentration and transfusion with restoration of arterial pressure and blood volume are measures which restore only a fraction of the normal renal blood flow. Concurrent measurements of the vasoconstrictor properties of plasma show that a vasoconstrictor substance appeared in it with the onset of renal ischemia. Such a substance also appears in animals subjected to bleeding or burns.[12] The demonstration of a vasoconstrictor in the plasma suggests that the vasoconstrictive ischemia is of humoral origin. A similar renal ischemia occurs in shock in human beings.[13]

Since even the early stage of shock, and more particularly of shock elicited by injury to skeletal muscles, is associated with an intense renal vasoconstrictive ischemia, it seems logical to attribute the phenomena of crush syndrome to persistent renal ischemia with resultant tubular renal injury.[14]

Unfortunately, in the dog, shock severe enough to result in intense renal ischemia is almost always fatal, so that nothing corresponding to crush syndrome was observed in a large series of experiments. Further, the muscles of dogs contain myoglobin, so that the question whether crush syndrome results from renal ischemia alone or from the coincidence of renal ischemia and myoglobinuria could not be answered. We therefore turned to studies in rats. The muscles of these animals do not contain much myoglobin. Their resistance to shock seems to be greater than that of dogs

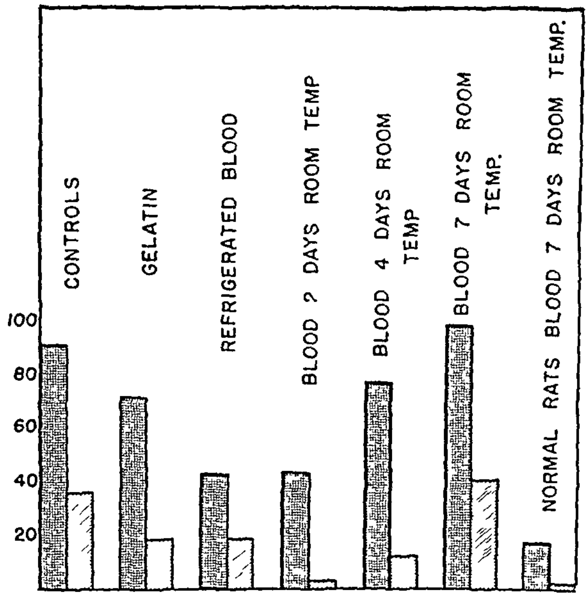

Chart 1.—Comparative levels of blood urea nitrogen and mortality (1) in normal rats given deteriorated blood and (2) in crushed, myoglobinuric rats treated with intravenous injection of gelatin and of blood under various conditions of preservation The blood urea nitrogen level (mg./100 cc., in the crosshatched columns) is the mean of observations made forty-eight hours after treatment The mortality (diagonally shaded columns) is given as the per cent of animals dying within seventy-two hours of treatment

Two groups of rats were subjected to crushing injury of one hind leg. One group received myoglobin solution intravenously one hour after release of the crush and the other, an equal volume of isotonic solution of sodium chloride.[15] Moderate azotemia was frequent in rats not given myoglobin and was accompanied by minor renal cytologic changes, notably cloudy swelling and the formation of hyaline casts. In contrast, severe and frequently fatal renal failure, accompanied with severe degenerative changes in the distal convoluted tubules and accumulation therein of pigment casts occurred in the group crushed and injected with myoglobin.[16]

We concluded that renal failure in crush syndrome is due to the coincidence of renal vasoconstrictive ischemia with myoglobinuria.

The mechanism of crush syndrome can thus be visualized. Vasoconstrictive renal ischemia occurs with the onset of shock or even of injury. The urine is acid and small in volume. The muscle cells are fragmented, so that when circulation is restored through crushed areas myoglobin diffuses into the blood, whence it is filtered into the renal tubules. Thus the conditions of pigmentary precipitation (aciduria, oliguria) are met, while the kidney is further damaged by lack of blood flow. It has been demonstrated[17] that hemoglobin precipitation in renal tubules is facilitated by prior injury, whether from ischemia or injection of a nephrotoxin (tartrate). However, it is not clear from these experiments whether the factor responsible was cellular injury as such or oliguria resulting therefrom. In either case the conditions of precipitation are present in crush syndrome.

III. *Hemoglobinuria.*—The participation of myoglobinuria in crush syndrome raises the question of hemoglobinuria and of its effect. This problem was explored in many of the early cases of crush syndrome, in which it was definitely shown that the patients' urinary pigment was myoglobin and not hemoglobin.[18] But 8 cases of renal failure have been reported following war injury,[19] in at least 2 of which the renal injury of the patients seems to have resulted from intravascular hemolysis following transfusion of compatible blood.

Gibson, Aub and Evans[20] and their co-workers have shown that refrigerated whole blood preserved in acid citrate medium can be transfused with complete safety (less than 10 to 20 per cent hemolysis of donor cells in four hours after transfusion). Short periods of exposure to room temperature greatly shortens the life of the transfused cells. Several days of such exposure need not result in visible hemolysis of the blood in the flask, but nearly all the cells of such blood may break down in less than four hours in the recipient's circulation, with resultant hemoglobinemia.

In collaboration with these workers we therefore examined the safety, as regards renal function, of blood stored under various conditions when transfused in normal rats with neutral and acid urine and in rats with one crushed limb. In some experiments the survival of donor cells was traced by tagging their hemoglobin with radioactive iron (Fe^{56}).

Results of these experiments are summarized in chart 1. Transfusion of sterile, refrigerated blood which has been preserved for one or two weeks greatly decreases the amount of renal injury which results from crushing and myoglobin injection in untreated rats. Exposure of such blood to room temperature for two days does not impair the benefit of the transfusion, unless the blood is contaminated by bacteria. Infected blood was almost instantly lethal in crushed rats.

The benefit due to transfusion in experimental crush syndrome is lost when the blood has been maintained at room temperature for four days, and blood kept at room temperature for seven or nine days is definitely injurious to crushed rats. The injury such blood causes is largely renal. Calculations made by Dr. Gibson show that in the rat, as in the human being, such blood is rapidly hemolyzed (chart 2) in the recipient's circulation. About 40 per cent of the hemoglobin present in the transfusion (50 per cent of that hemolyzed in the circulation) appears in the kidneys.

In strong contrast, transfusion of blood maintained at room temperature for more than a week under sterile conditions into normal rats did not cause either functional or anatomic renal injury.

It is therefore apparent, as the paper of Darmody and others[10] has suggested, that what seems to be crush syndrome may result from intravascular hemolysis. Blood not visibly hemolyzed but inadequately refrigerated may be lethal in injured subjects, although harmless enough in normal recipients.

IV. *Renal Toxins in Crush Syndrome: Allied States.*—The major renal lesion in crush syndrome is epithelial. Renal epithelium is sensitive to a variety of toxins. Thus, a cellularly toxic substance liberated into the blood during states of shock and injury might participate in the renal damage caused by renal ischemia and the precipitation of pigment. Most toxins injure the proximal tubule more than they do the distal. This hypothetic toxin would have to differ from known nephrotoxins in that it would act in the distal convoluted tubules, for it is in these that the renal injury of crush syndrome is concentrated. No such directly-acting cellular toxin has been demonstrated.

There may be a variety of vasoactive substances in the blood during shock and states of severe injury which tend to damage renal epithelium indirectly by depressing blood flow. The vasoconstrictor substance of shock[12] has been previously noted. Eggleton[21] has shown that from injured muscle something is released into the blood and partially destroyed in the liver and that this substance depresses renal function, presumably by decreasing renal blood flow. Bielschowsky and Green[22] suggested that adenosin pyrophosphate and similar substances liberated from muscle might account for some of the vascular collapse, including that of the kidneys. Bollman and Flock[23] have since shown that adenosine triphosphate cannot account for the effects of tourniquet shock. A vasoexcitor substance of supposed renal origin has been found in plasma in early shock.[24] But it would be inaccurate to refer to these as renal toxins, since their effect on renal function seems to be indirect and due to the renal ischemia they may provoke.

The case for the primacy of renal ischemia is not complete. The principal renal lesion which results from complete obliteration of renal arterial inflow is degeneration of the proximal convoluted tubules, which resembles that of cortical renal necrosis. The localization of renal damage in crush syndrome in distal tubules suggests that ischemia of crush syndrome must differ from that which follows clamping of the renal artery. We[10] have shown that renal blood flow is irregularly distributed during states of hypotension, and it may be that this irregularity of distribution accounts for the distal tubular localization.[24a]

Whatever the mechanism by which the injury concentrates in this site, it is increasingly evident that such damage occurs in a wide variety of conditions. In many of these the major cause seems to be liberation of heme-globin pigments into the blood (transfusion-induced hemolysis, burns, blackwater fever, other hemoglobinurias, crush syndrome and other myoglobinurias). But there are many states in which liberation of pigment into the blood is not a major concomitant (yellow fever, spirochetal jaundice, Asiatic cholera, typhus fever, postpartum shock, shock due to obstetric accidental hemorrhage, and that due to exposure to high altitudes). In these also renal failure may occur with distal tubular injury and accumulation in the tubules of variable numbers of casts, including some composed of pigment. Similar injury, usually without pigmentary cast accumulation, occurs in the anuria of delayed hepatorenal syndrome and in that of diabetic coma.

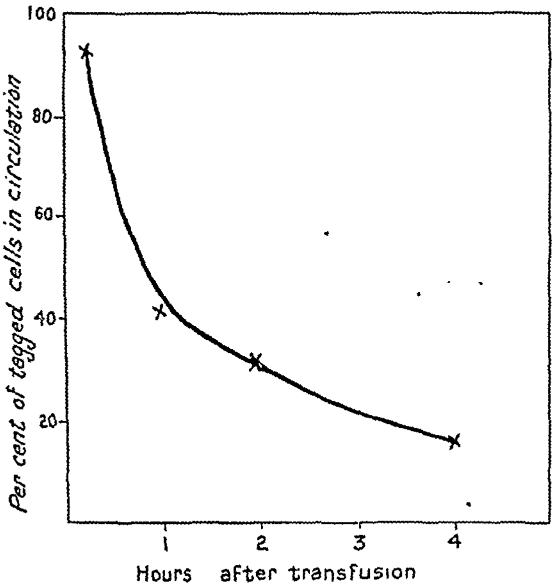

Chart 2.—Course of destruction in the recipient's circulation of transfused blood kept at room temperature for seven to nine days. (Data provided by Dr. John G. Gibson 2d.)

In most of these conditions there is widespread damage of tissue, and it may be assumed that vasoconstrictive renal ischemia is present. The pigment casts may form from intravascularly liberated hemoglobin or may form intratubularly from small glomerular capillary leak of red cells. The primary lesion is ischemia, and tubular obstruction and injury from the formation of casts is secondary and additive. Peters[25] has suggested that increased intrarenal pressure due to tubular obstruction and inflammatory edema is a further mechanism of renal damage in these disease states, although the evidence for this is incomplete. Thus, the mechanisms of what has been recently termed "lower nephron nephrosis" are probably multiple.

V. *Treatment.*—Treatment is directed toward the underlying mechanisms. These mechanisms in crush syndrome with myoglobinuria or hemoglobinuria are, in their probable order of significance, (*a*) vasoconstrictive renal ischemia; (*b*) myoglobinemia and myoglobinuria or hemoglobinemia and hemoglobinuria with (*c*) oliguria and (*d*) aciduria and (*e*) tubular cellular injury due to renal ischemia. In the allied states of anuria associated with distal tubular lesions but without pigmentary participation the factors responsible are apparently (*a*) renal ischemia and (*b*) resultant cellular injury.

The primary problem in both types of renal damage is renal ischemia. This renal ischemia is due to vasoconstriction. The vasoconstriction results largely from the action of a vasoconstrictor present in blood, which in our view is liberated from injured tissues. Thus the primary issue is to decrease the supply of vasoconstrictor by (1) slowing its absorption and (2) decreasing its formation.[26] The absorption of such a substance from injured tissue is slowed and the renal ischemia minimized by use of a compression bandage.[11] The formation of vasoconstrictor seems to be due in part to circulatory failure; consequently, it should be slowed by restoration of circulatory function, i. e., by transfusion and similar measures. It may be that refrigeration would decrease both formation and liberation of vasoconstrictor.

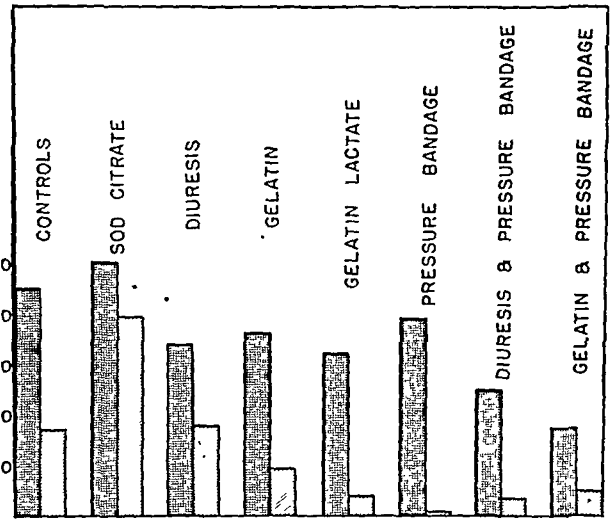

Chart 3.—Effect of various forms of treatment on experimental crush syndrome. Data are summarized as in chart 1.

Oliguria in these conditions is due in part to renal ischemia with decreased glomerular filtration and, it would seem, also to excessive reabsorption of water through injured tubular cells. It is countered by the restoration of blood volume and blood pressure, by decreasing renal ischemia and by the use of diuretics.

Aciduria in crush syndrome is due to absorption of acid metabolites from injured muscle. This absorption is slowed by application of pressure bandages. Urinary acidity may then be decreased by the supply of alkali, oral or intravenous, as sodium lactate, bicarbonate or citrate.

Finally, if there exists a nephrotoxin acting on the tubular cells from the tubular fluid, it is apparent that restoration of a rapid rate of urinary flow will decrease its local concentration.

Thus, the basic preventative measures in crush syndrome are (1) pressure bandaging of the injured limb, (2) rapid treatment of shock with restoration of blood volume and blood pressure, (3) provision of adequate fluid, (4) provision of a diuretic and (5) the administration of an alkali.

The efficacy of some of these measures in experimental crush syndrome may be judged from chart 3. The intravenous administration of diuretics in doses of 0.1 mg. per gram of body weight of mannitol or sucrose (approximately 5 to 10 Gm. in a human being) or sodium sulfate (the equivalent of 1 Gm. in a patient), definitely decreased the degree of renal injury. Intravenous injection of 4 per cent gelatin solution (the equivalent in a patient of about 1 to 2 liters of plasma) further decreased renal injury and also decreased mortality. Treatment with gelatin seemed slightly more effective when the solution was made up in sixth-molar sodium lactate solution rather than isotonic solution of sodium chloride. Tolerance of crushed animals to rapid injection of gelatin was increased by the addition of calcium lactate (the equivalent of 1 Gm. in a human being).

The best result in the prevention of crush syndrome in rats was obtained by application of a pressure bandage to the injured limb within an hour after release from the crush, together with intravenous injection of gelatin in sodium lactate with added calcium lactate.

Prompt transfusion of refrigerated blood was at least as effective as infusion of gelatin (chart 1).

The problem of urinary alkalinization has been widely discussed, and most recommendations for the treatment of crush syndrome and allied states include the liberal prescription of alkali compounds, intravenously and orally, in amounts totaling 30 to 40 Gm. daily. The recommended intravenous dose of sodium citrate is 5 Gm. In crushed, myoglobin-injected rats the intravenous injection of a comparable dose of sodium citrate (0.1 mg. per gram of body weight) often caused severe tetany which was either immediately fatal or which added to the shock and renal injury, to cause delayed and excessive mortality (chart 3). Sodium bicarbonate in equal dosage, although not as immediately toxic, was equally ineffective in preventing renal injury. Thus the prevention of crush syndrome by alkalinization alone is dangerous and unjustified. The dangers of alkali treatment in these states, particularly in blackwater fever, has been recently emphasized by Maegraith and Havard[27] who justly point out that it may be impossible for an injured kidney to form alkaline urine, so that pushing alkali therapy to the point of urinary alkalinization may lead to depression of renal function[28] and dangerous alkalosis.

Our recommendations for the preventive treatment of crush syndrome and allied states are (1) pressure bandaging of the injured area and (2) prompt treatment of shock by transfusion of blood or plasma, (3) together with the infusion of 1 or more liters of sixth-molar sodium lactate and the injection of a diuretic, such as sucrose or mannitol, in repeated doses of 5 to 10 Gm. or of sodium sulfate in a dose of 1 Gm. intravenously.

Unfortunately, once the damage has been done to the kidney, the evolution of the renal injury is largely unaffected by treatment, which is supportive. Renal decapsulation has been advocated for the relief of increased interstitial pressure.[29] It is not clear that this mechanism is always significant. The value of decapsulation is not easily assessed in a disease which tends in a large number of cases to recede spontaneously at the end of one week. Histologically, the kidneys in experimental and clinical crush syndrome show extremely active regeneration of tubular cells in injured areas. Therefore, were it possible to maintain life during the period of renal injury until sufficient regeneration had occurred, it is possible that recovery would then be assured. Peritoneal dialysis[30] may answer this requirement.

---

[26] Our observations indicate that provision of renal vasodilators is harmful. The aim is to prevent vasoconstriction rather than to cause vasodilation.

SUMMARY

Post-traumatic anuria (crush syndrome) is a special instance of a group of related states of renal injury. These fall in two groups, namely, those in which the principal lesion is obstruction of the renal tubules by pigmented (myoglobin, hemoglobin) casts and those in which the injury lies principally in necrosis of the epithelium of the distal convoluted tubules. The underlying mechanism in all of these, and especially in those associated with trauma to muscle tissue, is vasoconstrictive renal ischemia. This ischemia results in oliguria, which, associated with aciduria, predisposes to precipitation of pigment casts. Tubular injury due to ischemia and a hypothetic toxic agent may contribute to the renal damage.

In the presence of such renal ischemia, myoglobinuria and hemoglobinuria, which cause little injury under normal conditions, result in severe renal injury. Attention is directed to the danger of transfusing blood which has been inadequately refrigerated.

Treatment of crush syndrome and the related states is preventive and consists in the prevention of renal vasoconstrictive ischemia by prompt treatment of shock (transfusion of blood or plasma), the lessening of absorption from areas of injury by pressure bandaging and the establishment of a rapid rate of urinary flow by the administration of a diuretic. Urinary alkalinization is advisable, but vigorous treatment with alkalies is dangerous.

ADDENDUM

Since this manuscript was submitted, it has been shown by direct means that stimulation of renal vasomotor nerves results in a change in the pattern of renal blood flow by which the cortex, which normally receives most of the renal blood flow, becomes ischemic, the stream being diverted into the medulla.[31] It has been suggested that this vasomotor mechanism may underlie the renal cortical ischemic injury of crush syndrome and allied states and that the prevention of renal injury due to this mechanism may be accomplished by procedures which block renal vasomotor pathways (splanchnic block, high spinal or caudal anesthesia).

Our failure to demonstrate an important vasomotor participation in experimental crush syndrome may result from our observations having been made in anesthetized animals. In these, by indirect means, we had shown[10] that some redistribution of cortical blood flow occurs in the renal ischemia due to bleeding or tourniquet shock. This renal ischemia was only slightly affected by renal denervation. It thus seems likely that the humoral vasoconstrictors of severe shock act on the renal circulation in a manner similar to that of intense vasomotor stimulation, i. e. by causing constriction of the cortical interlobular arteries, with cortical ischemia and diversion of blood into the medulla. Clinically, the use of procedures which block renal nerves should therefore be explored in the early treatment of crush syndrome and related states. The nature of the renal lesions does not suggest that such treatment will be of avail once renal ischemic damage and pigmentary occlusive and toxic injury are well established.

An authoritative study of crush syndrome and related renal lesions has been published by Lucké.[32]

EXTRARENAL AZOTEMIA AND TUBULAR DISEASE

E. T. BELL, M.D.
and
ROBERT C. KNUTSON, M.B.
Minneapolis

Extrarenal azotemia may be defined as a pronounced retention of nitrogenous metabolites not caused by disease of the kidneys. The term azotemia seems preferable to uremia, since the clinical signs of uremia are not always present. This form of azotemia is not a circumscribed entity but a condition which may result from a number of unrelated causes. The essential features are oliguria or anuria, azotemia, and no anatomic lesion in the kidneys sufficient to explain renal insufficiency.

In hospitals in which routine determinations of blood urea are made during the last few days of life a surprisingly large number of patients will be found to have an elevation of blood urea to uremic levels. This report is based on a study of 84 cases of this type in which the blood urea nitrogen concentration of the patient attained a level of 50 mg. per hundred cubic centimeters or higher before death. In most instances the renal tubules show no structural changes, but often they show hydropic degeneration and, infrequently, other degenerative changes which may be partly or entirely responsible for renal failure. For this reason it is difficult to make a sharp differentiation between true extrarenal azotemia and azotemia due to tubular injury.

The cases have been arranged in several groups in accordance with etiologic factors which seem to be of major importance, but often more than one influence is present and there remains a large miscellaneous group in which the etiology has not been clearly established.

I. AZOTEMIA FROM DEHYDRATION

Azotemia from dehydration[1] (table 1) results from (*a*) decreased fluid intake, (*b*) intestinal obstruction and (*c*) excessive diarrhea.

A. *Decreased Fluid Intake.*—When an animal is deprived of water the diuresis decreases gradually and

the urine becomes more concentrated. Finally there is complete anuria, and the blood urea increases to uremic levels. All the fluid is withdrawn from the tissue spaces, and the animal has a shrunken dehydrated appearance. The tissue spaces are emptied of fluid, but the blood will not give up any fluid to form urine when to do so would seriously reduce the blood volume.

In table 1 are tabulated 6 cases in which the azotemia was due to a decreased intake of fluid. In cases 1, 2, 3 and 5 the patients could not take fluid because of obstruction of the stomach, and in cases 4 and 6 fluid was refused because of the mental state. Only a little fluid was administered to any of these patients by the parenteral route.

In no instance of this group was there any enlargement of the kidneys, and microscopically the renal tubules were entirely normal. These 6 cases appear to be instances of true extrarenal uremia due to a decreased intake of fluid.

B. *Intestinal Obstruction*.—Dehydration from intestinal obstruction[2] (table 1) occurs most frequently from obstruction of the small intestine, less often from pyloric obstruction and paralytic ileus, and it is due in most instances to excessive loss of fluid by vomiting. So much fluid is lost in the vomitus that the patient becomes dehydrated and oliguria ensues. Chlorides are also lost excessively, and the blood chloride falls well below the normal level. For this reason the term hypochloremic uremia has been used. It was formerly believed that the loss of chloride caused retention of urea to maintain the osmotic pressure of the blood; but Kerpel-Fronius in a series of papers showed clearly that the azotemia is due to dehydration and not to low blood chloride. Experimentally he produced hypochloremia without azotemia, and he showed that in azotemia with hypochloremia the former may be corrected by the administration of water without salt. Chlorides correct the alkalosis but not the azotemia. Mach and associates found that in cirrhosis of the liver repeated drainage of the ascitic fluid reduced the blood chlorides as low as 300 mg. per hundred cubic centimeters without producing any elevation of blood urea.

In table 1 are shown 6 cases in which intestinal obstruction appears to be the major cause of the azotemia. In cases 7 to 11 there was excessive vomiting; but there was none in case 12. Possibly the accumulation of fluid in the intestinal tract may be sufficient

to cause dehydration of the tissues. In case 9 the low blood pressure of the patient was probably contributory to the oliguria and azotemia. In case 8 the kidneys were swollen, but in no instance in this group were there any structural alterations in the renal tubules.

C. *Excessive Diarrhea.*—In Asiatic cholera the dehydration, oliguria and azotemia are due to loss of fluid through the intestine. In table 1 3 cases are shown in which the azotemia was attributed to excessive loss of fluid from diarrhea. In cases 13 and 15 the renal tubules are normal, but in case 14 there is a severe hydropic degeneration of the tubules (fig. 1). In this instance it appears that the tubular injury is as important as the loss of fluid in causing the azotemia.

Unfortunately there are only a few observations on the specific gravity of the urine in the dehydration group, but they are perhaps sufficient to show that the urine is not always as concentrated as one might expect. It has been noted in several instances of azotemia due to dehydration that the administration of large quantities of fluid parenterally may increase the diuresis without increasing the specific gravity of the urine or lowering the level of the blood urea. These observations suggest that the renal tubules are injured in dehydration azotemia, but they showed structural changes in only 1 of 15 cases.

II. AZOTEMIA FROM LOW BLOOD PRESSURE

In the second group (table 2) there are listed 20 cases in which the azotemia was probably due in large measure to low blood pressure.[3] In each instance the blood pressure was extremely low during the last day or two of life. When the systolic pressure falls to 80 mm. of mercury or lower glomerular filtration is reduced and *the glomerular filtrate is almost entirely* reabsorbed in the tubules. There is also the factor of anoxia associated with the decreased flow of blood to the renal tissue This is the condition which prevails in shock and all these patients were in a state of shock terminally. In case 17 the shock was due to a massive intraperitoneal hemorrhage. It will be noted that in 5 cases, 31 to 35, the shock was due to fractures.

---

[3] Evans, T. S.: Azotemia with Normal Kidneys Found Post Mortem, Arch. Int. Med. 48: 1231 (Dec.) 1931.

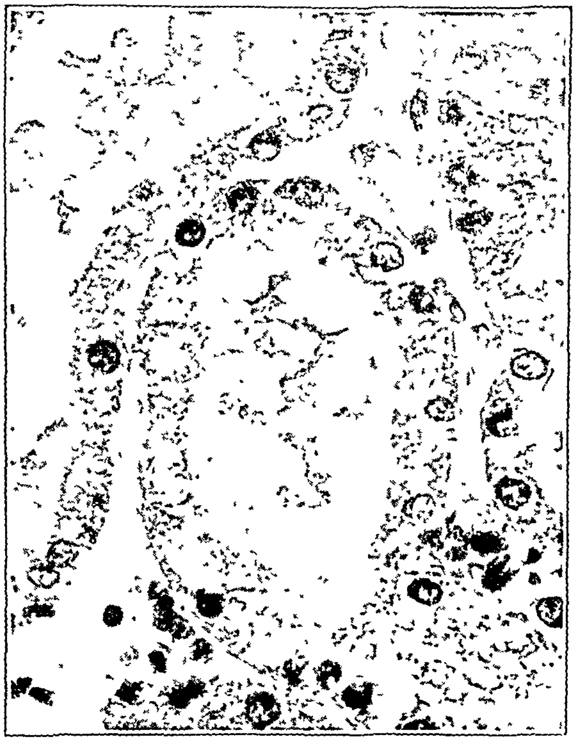

Fig 1 (case 14, table 1) Severe hydropic degeneration of the renal tubules

In 14 cases the renal tubules appeared normal histologically, but in 6 instances there was a mild hydropic degeneration, which suggests that tubular injury may have been a contributory cause of the oliguria and consequent azotemia.

III. POSTOPERATIVE AZOTEMIA

The third group, postoperative azotemia[4] (table 3), is not a well-defined group from the point of view of causation, since more than one influence may be concerned. One factor which is often operative is postoperative shock with a fall of blood pressure. There may also develop some complication such as pneumonia or ileus. It is important to note that 5 of the 10 cases listed in table 3 showed hydropic degeneration of the renal tubules indicative of tubular injury (fig. 2). In case 43 the hydropic degeneration was severe, and there were small areas of necrosis in the liver.

Reflex oliguria: Occasionally after surgical operations, especially on the ureter, kidney, bladder, lower colon and gallbladder, severe oliguria and azotemia develop. The renal function prior to operative intervention is normal, there is no postoperative fall of blood pressure, and the kidneys are not traumatized. The blood urea may rise to uremic levels. The diuresis is usually reestablished after a few days of anuria, and operative intervention is not indicated. It has been suggested that the suppression of urine is due to *overactivity of the* sympathetic nervous system, such as occurs in paralytic ileus.

In case 45 anuria developed in the patient following bilateral retrograde pyelograms. In order to start a diuresis large quantities of fluid were given intravenously. The patient died on the third day from edema of the lungs.

IV. MISCELLANEOUS CASES OF EXTRARENAL AZOTEMIA

The fourth group constitutes miscellaneous cases of extrarenal azotemia, which occurs in the terminal stages of a large variety of diseases. These have been grouped to some extent in table 4. In the cases of heart disease[5] (cases 46 to 54) low blood pressure was apparently not a factor, and the fluid intake was satisfactory. The urine was not highly concentrated, but the renal tubules were normal on histologic examination. No cause of the azotemia is apparent.

In the cases of pneumonia and empyema (cases 55 to 63) hydropic degeneration of the tubules was found in 4 instances, but in 1 of these (case 63) sulfadiazine may have been responsible. There is, however, a suggestion that suppuration may produce tubular injury.

In this miscellaneous group the cause of the azotemia is not clear. In patients with a satisfactory fluid-intake and a normal blood pressure azotemia may develop during the last few days of life. This terminal azotemia occurs frequently. It appears that 25 per cent of persons dying of such diseases as lobar pneumonia and cancer show blood urea at uremic levels on the last day of life. It has been suggested that increased destruction of tissue proteins is partly responsible for this terminal uremia. It is important to remember that

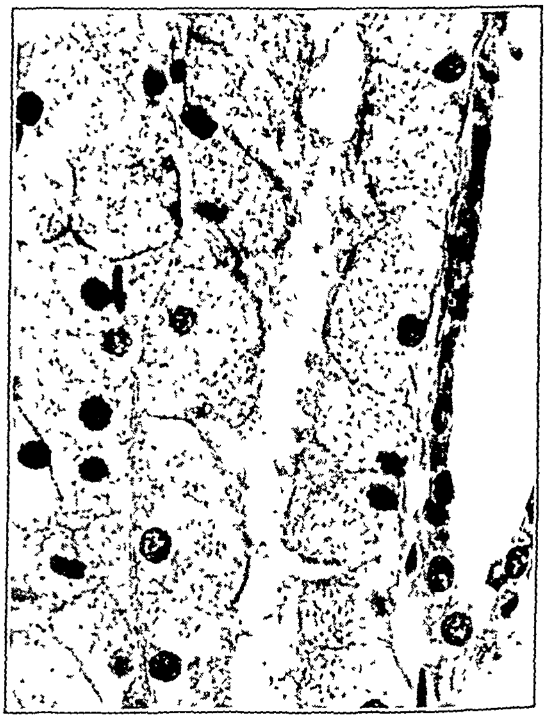

Fig 2 (case 37, table 3).—Hydropic degeneration of the renal tubules indicative of tubular injury.

---

[4] Bannick, E G, and Keith, N M: M. Clin North America **11:** 1571, 1928.

[5] Kartagener, M Klin Wchnschr **1:** 1028, 1933

a terminal rise of blood urea does not indicate a primary renal disease.

Azotemia is a frequent complication of diabetic coma[6] (cases 81 to 83). About twenty-four to forty-eight hours after the onset of coma oliguria or anuria develops. Under treatment the patient may recover from the coma and the hyperglycemia and acidosis may be corrected, yet the anuria may persist. At autopsy the kidneys are frequently swollen, but the microscopic changes are hardly sufficient to explain the anuria. It has been suggested that the tubules are injured from the acidosis or the low blood pressure, and that the disturbance is of a functional nature.

OTHER FORMS OF EXTRARENAL AZOTEMIA

There are other forms of extrarenal azotemia which are not represented in the 84 cases here reported.

Azotemia from Hemorrhage into the Gastrointestinal Tract.—Massive hemorrhage into the gastrointestinal tract,[7] usually from bleeding ulcers, causes an increase of blood urea sometimes to uremic levels. There is oliguria and sometimes anuria. The urine may show a good concentration of urea, but the specific gravity is not high (around 1.022) and may be as low as 1.012. The several factors to which this form of azotemia has been attributed are: absorption of blood from the gastrointestinal tract, low blood pressure and decreased blood volume.

Borst attributed azotemia to the rapid absorption of urea formed from the blood in the intestinal tract, and this interpretation has been adopted by others. However, Johnson gave 1,200 to 1,500 cc. of blood to 4 different patients by stomach tube during a period of six to eight hours. The blood urea rose only moderately and transiently, except in 1 patient whose urea clearance was only 50 per cent of normal, in which instance it reached 54 mg. per hundred cubic centimeters. The absorption of blood would help to explain the azotemia but not the oliguria.

It appears more probable that the azotemia is due to the combined effect of low blood pressure, which is often present, and the dehydrating effect of the hemorrhage. After a hemorrhage, fluid is withdrawn from the tissue spaces to restore the blood volume and none is available for the formation of urine.

The Crush Syndrome.[8]—Bywaters, Beall and others have reported over 20 cases of oliguria and azotemia following crushing injuries of an extremity sustained during air raids. On admission the patient is usually in good condition except for the swelling of the crushed extremity. The extremity usually does not become gangrenous, but some of the muscle is necrotic. The hemoglobin is increased and the patient is thirsty, indicating a loss of fluid into the swollen extremity, as in a severe burn. Shock may develop, but this does not always occur. Diuresis becomes progressively less, hypertension and azotemia develop and the patient may die of uremia, or recovery may follow the onset of diuresis. Some of the patients pass a dark-colored urine which gives a positive benzidine reaction and shows the bands of myohemoglobin on spectroscopic examination. At autopsy the kidneys are swollen and edematous. The investigators attribute the azotemia chiefly to tubular injury, especially injury of the distal convoluted tubules. The structural changes in the tubules seem hardly sufficient to explain the anuria, yet the clinical evidence indicates that their function is seriously impaired.

Paxson and associates described 3 cases of urinary suppression: 1 from a retroplacental hematoma, 1 from rupture of the uterus and 1 from infarction of a cystic ovary. They regard these as similar to the crush syndrome.

Azotemia from Subarachnoid Hemorrhage.—In occasional instances of subarachnoid hemorrhage[9] blood urea is increased to uremic levels. This is a transitory phenomenon and no satisfactory explanation is available (Romcke and Skouge).

COMMENT

Extrarenal azotemia may be brought about by several different mechanisms, and the pure extrarenal types cannot be separated sharply from urinary suppression due to tubular injury. Anuria and oliguria are symptoms of severe tubular injury, and there can be no doubt that tubular injury is responsible for urinary suppression in such diseases as mercuric chloride poisoning and some cases of anuria following sulfonamide therapy and blood transfusions, in which striking degenerative changes in the tubules are visible. In 20 of the 84 cases on which this study is based there was mild to severe hydropic degeneration of the proximal convoluted tubules, indicating that tubular injury may have been in part or entirely responsible for the uremia. In 2 of these 20 cases sulfadiazine was probably the cause of the injury to the tubules. In the other 64 cases there were no demonstrable changes in the tubules. When the tubules appear normal histologically one may believe that their function is also normal, or it may be maintained that functional failure may occur without alterations of structure that we are able to recognize.

It seems clearly established that low blood pressure and dehydration of any type may produce azotemia, and since neither of these mechanisms involves failure of the tubules one does not expect to find tubular degeneration. Likewise in reflex anuria the tubules are not primarily concerned.

The terminal azotemia which occurs so frequently in a large variety of diseases cannot be explained entirely as due to dehydration and low blood pressure. An increased tissue catabolism during the last days of life may be partly responsible for the increased level of urea in the blood. Toxic substances derived from necrotic and inflammatory tissues may injure the renal tubules sufficiently to cause oliguria without producing structural alterations that can be recognized.

The specific gravity of the urine has not been studied sufficiently, and our observations are inadequate. The few determinations that were made indicate that the urine is seldom concentrated even in the presence of severe oliguria, which indicates that the process is not one of simple dehydration. When the diuresis is low and the glomerular filtrate moves slowly through the tubules it is possible that more of the crystalloids are reabsorbed or that more urea diffuses back into the blood. Much could be learned from chemical study of the urine.

The creatinine increases in the blood corresponding with the increase of urea. Extrarenal uremia cannot be distinguished from uremia of renal origin by the creatinine level.

The few observations available indicate that the carbon dioxide combining power of the plasma decreases as the blood urea level rises, as in renal uremia.

SUMMARY

Eighty-four cases of terminal azotemia are reported in which the blood urea nitrogen ranged from 50 to 205 mg. per hundred cubic centimeters. In 20 cases there was mild to severe hydropic degeneration of the proximal convoluted tubules indicating that tubular injury may have been partly responsible for the azotemia.

A terminal rise of blood urea nitrogen to uremic levels occurs in a high percentage of persons and in a number of different diseases.

A high blood urea nitrogen level on the last day of life does not mean that the patient has a primary renal disease.

In these 84 cases the azotemia is attributed to dehydration in 15, to low blood pressure in 20 and to postoperative complications in 10 cases. Three cases were associated with diabetic acidosis and 1 with necrosis of the liver. In the remaining 35 cases the cause of the azotemia could not be established.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. MOON, DRS. MARTINEAU AND HARTMAN, DRS. CORCORAN AND PAGE AND DRS. BELL AND KNUTSON

Dr. E. T. Bell, Minneapolis: Our knowledge of extrarenal uremia is incomplete. We know that dehydration and low blood pressure account for many cases, but for the majority we have no adequate explanation. Dr. Corcoran has shown that some cases are due to vasoconstriction. Apart from these three forms, we still have a large group of cases, especially those that come on during the last few days of life, about which we have practically no ideas. The blood pressure is normal, and the patient is well hydrated, and yet uremia develops. The kidneys appear normal. Work on this problem has really just begun. We must try to find out why the uremia develops. Is it entirely the fault of some mechanism outside the kidneys, or do the kidneys really play a role? Better methods are needed for study of the histology of the tubules. Unless the tissue is fresh and the fixation good even normal tubules appear to be damaged, and many pathologists have been misled by artefacts. We also need to know what functional changes take place in the kidneys in extrarenal azotemia. Why cannot the kidneys concentrate the urine in the presence of oliguria? These are some of the points on which we would like to have more information.

Dr. A. C. Corcoran, Cleveland: This symposium has established the occurrence in a wide variety of diseases of a common clinical and functional pattern of renal damage characterized by tubular necrosis and degeneration in association with variable numbers of pigmented casts. In some cases the casts are few and apparently noncontributory, and in others they are many and a major factor in the renal damage. The lesions which occur in the absence of any large number of pigmented casts we would view as due primarily to renal vasoconstriction of humoral origin and consequent anoxia. The deposition of pigment may be added to this. Our experience indicates that even minor degrees of vasoconstrictive renal ischemia greatly facilitate the intratubular deposition of pigment. In treatment, urinary alkalinization by the intravenous injection of sodium citrate is often recommended. However, such an injection is often lethal in rats with crushed limbs, apparently by addition of tetany to preexisting shock. If alkalinization is to be attempted, and there is much to suggest its value, it should be accomplished cautiously and by injection of sodium lactate rather than sodium citrate.

Dr. Virgil H. Moon, Philadelphia: I wish only to reemphasize one or two items. Vasoconstriction is certainly a factor in many instances; in all forms of secondary shock, vasoconstriction is one of the compensatory mechanisms which the body has called into play to sustain the circulation at an adequate level, and that vasoconstriction in itself may produce anoxic changes in the kidney. These may be so severe as to cause degenerative changes in the tubules. Some of the cases which it was my privilege to study were those in which aviators at high altitudes, supplied with oxygen masks, succumbed to anoxia by some accident happening to the oxygen apparatus. Perhaps moisture froze within the mask; perhaps the lines were cut by flak or otherwise. Those who died of acute anoxia—death probably occurred within fifteen minutes from the time when lack of oxygen became pronounced—showed parenchymatous degeneration of the kidneys. This was of the same type but not of the same degree as that seen in the cases of longer duration. In regard to terminology: it is not the physician's function to attach names to things, but it would be advantageous if this item which has been rediscovered recently by physiologists, pathologists and internists should receive a designation. It would be historically appropriate if this were called acute parenchymatous nephritis, although it is not truly an inflammatory condition as would be implied by "itis." Other appropriate terms would be acute nephrosis or acute tubular disease. The cases described could accurately be termed acute tubular disease.

DERMATITIS DUE TO QUINACRINE HYDROCHLORIDE ("ATABRINE")

THOMAS W. NISBET, M.D.
Pasadena, Calif.

The purpose of this presentation is to recapitulate the cutaneous manifestations which occur following the administration of quinacrine hydrochloride ("atabrine *di*-hydrochloride" N. N. R.). In the past eight months numerous articles have been presented or published, chiefly dealing with the lichenoid type of cutaneous reaction. This type has been variously described as atypical hypertrophic lichen planus, New Guinea disease or tropical lichen planus. Since practically all the published observations on this type of reaction are in accord, it will be considered only briefly; although exceedingly interesting to dermatologists, it comprises only a small percentage (about 12 per cent) of the dermatoses produced by this drug.

Soon after the beginning of the New Guinea campaign it became apparent that cutaneous disorders were a prolific source of trouble in the Southwest Pacific area. Many conflicting ideas were expressed. The average soldier soon came to call every cutaneous eruption "jungle rot." The medical officer tended to ascribe the conditions to fungi, especially when the hands, feet and groin were involved. Contact dermatitis became a favorite diagnosis as more and more troops came into intimate contact with the profuse vegetation of the jungle. Sensitivity to sunlight or a pellagroid reaction was considered in those cases in which the eruption first appeared on the exposed areas of the body. Impetigo, pyoderma and erysipeloid eruption became favorite diagnoses in one group of these cases. The otologist

Read before the Section on Dermatology and Syphilology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

encountered many cases of otitis externa, which he generally considered as tropical mycosis. If a little dandruff was present a diagnosis of seborrheic dermatitis was entertained. Cases of generalized exfoliative dermatitis, severe and not infrequently fatal, began to appear in persons who had not received arsenical drugs. All of these factors, combined with the injudicious topical use of the sulfonamide compounds, ammoniated mercury and ointment of benzoic and salicylic acid, carbolfuchsin paint and other similar remedies, together with the effects of a tropical climate, produced a picture that was indeed confusing. As more cases were seen and various factors considered, it became apparent that there was only one in common, namely quinacrine hydrochloride. In the course of time it became possible to classify these cutaneous reactions in three groups: the eczematoid, the hypertrophic lichenoid and the generalized exfoliative.

First is the eczematoid group, which comprises about 80 per cent of the cases and which was overlooked by all except those who had seen service in the tropical areas of the South Pacific.[1] This reaction is characterized by a chronic, dry or exudative, symmetric, localized or generalized eczematous eruption. It is extremely recalcitrant to treatment, and its course generally is marked by periods of remission and exacerbation, though it may be steadily progressive. The sites of predilection are the ears, eyelids, periorbital region, the dorsa of the hands and feet and those areas most often affected in seborrheic dermatitis. On involution peculiarly pigmented flat or hypertrophic lichenoid lesions may develop at the sites of healing lesions. In some cases the eruption appears primarily as a pyogenic infection in the bearded region, the scalp and eyebrows or in the pubic area. On involution these lesions often produce a patchy alopecia. An alopecia totalis may occur.

The second group constitute the lichenoid reactions. This is the type which was most familiar to dermatologists in this country and Australia and about which a great deal has been written. Actually this group of reactions comprises only about 12 per cent of the total incidence of this cutaneous complex. While the eruption in these cases may closely resemble, both morphologically and histologically, that of a hypertrophic lichen planus, it has a more widespread and different distribution, often involving face and trunk or the palms and soles. Involvement of the nails is common, often producing changes similar to those of psoriasis or mycotic infections. In other cases there is a slate-blue pigmentation of the nail bed. Extensive lesions resembling leukoplakia or those seen in lichen planus are common on the mucous membranes of the mouth. Pigmented lesions without apparent changes in the texture of the mucous membranes are frequently seen in the same location. The eruption elsewhere varies from flat pigmented macules, in which the texture of the skin is normal, to thick, confluent, nodular, hyperkeratotic or verrucous lesions, the color of which ranges from pink to a deep violaceous hue.

The third group is the exfoliative reaction, which presents a severe exfoliative dermatitis resembling that due to the arsenobenzols. Secondary infection is common, and some fatalities occurred before penicillin became available. This type is occasionally primary but frequently secondary to the lichenoid or eczematoid forms.

INCIDENCE

Since all information concerning the untoward effects of quinacrine hydrochloride was suppressed during the war, no accurate statistics as to the actual incidence of dermatitis due to this drug are available. However, it was unquestionably high, as is shown by the following facts: In 1943, when there were comparatively few troops stationed in the Southwest Pacific, this theater of action alone accounted for 66 per cent of the total number of patients evacuated from all theaters of war on account of diseases of the skin. Practically all these cases originated in New Guinea, where "atabrine" discipline was rigidly enforced. In 1944 20 per cent of hospital admissions in New Guinea and a slightly lower percentage of evacuations of noneffective persons to the United States were on account of dermatologic conditions. At the same time it was commonly found that as high as 50 per cent of the men reporting for sick call in unit dispensaries did so on account of diseases of the skin. It is my opinion and that of other observers that from 80 to 90 per cent of these cases, though classified under various diagnoses, were in reality cases of dermatitis due to quinacrine hydrochloride.

CONTROLS

Due to the fact that exacerbation did not occur immediately on readministration of quinacrine hydrochloride, there are those who have doubted the role of this drug in the disorder. However, there are a large number of controls present, if one wishes to look for them. These are as follows:

1. American prisoners of war in the Philippines. It is a singular fact that in all the several thousand Americans who were prisoners of the Japanese after Bataan and Corregidor there has not been 1 instance of the cutaneous disorder described in this paper. These prisoners were on starvation diets which produced the wet and dry forms of beriberi. They suffered from pellagra, dysentery and malaria. Further, they lived, perspired and worked in a tropical climate. It is exceedingly strange that these "x" factors of some of the authors were unable to produce the entity previously described in the absence of the ingestion of quinacrine hydrochloride.

2. Military personnel. In troops and Navy personnel serving under identical conditions in the malaria-free areas of the tropical South Pacific where no quinacrine hydrochloride was administered, instances of this entity were not encountered.

3. Japanese prisoners of war. Until the proper authorities publish their reports on the number, physical condition and incidence of skin diseases of the Japanese taken prisoner by the American forces, no reliable data can be given. It is my impression that the Japanese soldier under identical conditions of tropical warfare but without benefit of quinacrine hydrochloride did not present this cutaneous symptom complex.

4. Mediterranean theater of operations. It has been stated that this symptom complex did not occur in the Mediterranean area even though certain units were in malaria-infected districts and the troops were taking quinacrine hydrochloride. However, this is not the case, and several examples of the lichenoid types of eruption occurring in British soldiers have been presented before the Section on Dermatology of the Royal Society of Medicine, although the causative factor of

---

[1] Novy, F. G., Jr.. Personal communication to the author.

quinacrine hydrochloride was not recognized.[2] It has also been reported from every other theater of war where this drug was used as a suppressive for malaria.

CONTACT DERMATITIS

One case of contact dermatitis of the eyelids in a nurse handling quinacrine hydrochloride has been reported.[3] The cases of contact dermatitis, rhinitis, bronchitis and asthma in pharmaceutic workers, as reported by Watrous,[4] are of interest in this regard. He stated that in a large laboratory in over 70 per cent of the men who handled the dry drug these conditions developed within a period of eight months. He further stated that "the potency of quinacrine as a local irritant is such that even with elaborate dust control equipment . . . a wide variety of symptoms were observed in the workmen."

OTHER UNTOWARD EFFECTS OF QUINACRINE HYDROCHLORIDE

Any drug producing such severe cutaneous reactions as does quinacrine hydrochloride must of necessity also cause damage elsewhere in the body. Thus it is known that hepatic damage occurs, which may end in death.[5] It is not without significance that most cases of severe hypoplastic anemia in troops in the Southwest Pacific area have been associated with so-called atypical lichen planus.[6] Acute quinacrine intoxication has been reported.[7] Disturbance of vision with advanced impairment of eyesight has been attributed to this drug.[8] The entire question of psychosis occurring in troops under suppressive therapy with this agent needs further study and reexamination in the light of recent work.[9] It is of interest, though uninformative, to note that there has been only one communication dealing with the untoward effects of the drug in pharmaceutical and manufacturing plants.[4]

MECHANISM OF PRODUCTION OF REACTIONS

Those immediate reactions to quinacrine hydrochloride, such as generalized pruritus, urticaria or exfoliative dermatitis, which occur in a small percentage of persons shortly after beginning treatment with the drug, can be considered allergic in character. Also, the scarlatiniform and morbilliform eruptions occurring in the first few days of treatment can be explained on a biotrophic basis and considered as examples of Milian's ninth day erythema. However, in the vast majority of cases in which the appearance of the eruption is delayed for many weeks or months after beginning the routine administration of quinacrine hydrochloride it can hardly be attributed to either an allergic or biotrophic reaction. The known cumulative effect of the substance with its long retention in the body; the hepatic damage, hypoplastic anemias, inanition, gastrointestinal symptoms, mental disturbances and transient paralysis which frequently accompany the cutaneous manifestations, all strongly suggest a toxic reaction. This would also account for the negative results obtained in intradermal and patch tests and for the frequent delay in the exacerbation of the eruption after the readministration of the drug.

Incidentally, the newer synthetic antimalarial (chloroquine SN 7618[10]), which is apparently a better drug than either quinine or quinacrine, is known to produce lichenoid lesions.

In view of the great difficulty in explaining the causation of quinacrine dermatitis by any of the present theories of drug-induced eruptions, it would seem that the entire problem of their etiology might well be subjected to critical reexamination.

TREATMENT

Preventive.—Owing to its cumulative effect, in a large percentage of normal persons toxic manifestations will eventually develop from even small doses of quinacrine hydrochloride if it is given over a long period. For this reason, the successful use of this drug as either a suppressive or therapeutic agent in malaria is entirely dependent on the early recognition of these toxic symptoms and the immediate discontinuance of the drug. In patients receiving this agent, the appearance of any lichenoid or eczematoid eruption, a pruritus or an urticaria, however slight, should be considered as a warning signal and as potentially dangerous. In these cases the drug should be discontinued immediately, quinine being substituted if necessary. All other actively toxic drugs such as arsenic, mercury, gold or sulfonamide compounds are contraindicated. Extension of the eruption or exfoliative dermatitis may follow the use of the sulfonamide drugs either locally or internally. Two cases of the relatively benign lesions of the lichenoid type were seen in which a fatal aplastic anemia followed the intramuscular injections of a bismuth or mercury compound.

Eczematoid Type.—The treatment in the eczematoid types of dermatitis is that of any other irritable dermatosis. Only the blandest local medicaments should be used. If moist dressings are required, weak solutions of potassium permanganate, aluminum acetate or isotonic solution of sodium chloride are indicated. Soothing lotions, such as Mook's or calamine, are useful in the moist eczematous forms, and simple ointments in the dry scaly types. The secondary infection, which may be a serious problem in these cases, should be controlled by the use of penicillin, given either locally or by intramuscular injection. It is of great value, especially in the severe generalized exfoliative or eczematoid types. It should be continued in small maintenance doses of from 80,000 to 90,000 units until the infection disappears. Untoward reactions to penicillin used in this manner were extremely infrequent in a large series of cases, and none were of a serious type. The results of penicillin therapy are particularly spectacular in the severe exfoliative forms, greatly reducing the nursing care required by rendering unnecessary the prolonged tub baths and continuous moist dressings formerly used.

[10] Loeb, R. F., and others: Activity of a New Antimalarial Agent, Chloroquine (SN 7618), J. A. M. A. **130**: 1069 (April 20) 1946.

Lichenoid Type.—The lichenoid type of reaction requires little treatment other than the cessation of the drug and the usually supportive measures, such as a high caloric and high vitamin diet. If pruritus is present the use of mild antipruritic ointments is indicated. In recalcitrant cases superficial roentgen therapy is of value.

CONCLUSIONS

1. Quinacrine hydrochloride ("atabrine *di*-hydrochloride" N. N. R.) is the etiologic agent in a large group of cutaneous conditions occurring in troops serving in the tropics.

2. The eczematoid type of reaction to this drug is the commonest and has been overlooked to a large extent.

3. The lichenoid type of reaction presents a bizarre picture of peculiarly pigmented, slate-blue to purplish hypertrophic lichenoid lesions.

4. The exfoliative type of reaction may occur primarily or as a progression of the eczematoid or lichenoid types.

5. In the mechanism of the production of this cutaneous syndrome, none of the generally accepted theories of drug-evoked eruptions appear adequate to explain the observed facts.

ABSTRACT OF DISCUSSION

Dr. James R. Drake, San Francisco: I should like to compliment Dr. Nisbet not only on his paper but on his early recognition of an important group of cases in the early phases of military activities in the southwest Pacific. It has been somewhat difficult to prove the role of quinacrine hydrochloride in this regard from a strictly scientific point of view. Many clinical workers in both the Army and Navy have attempted to produce exacerbations with readministration of the drug, with varying results. In my group, the eczematoid type flared fairly promptly and with a fair degree of regularity, while the lichenoid did not. Ingestion of the drug over a longer period of time was apparently necessary. Similarly, the antimalarial was taken for a longer period of time prior to the onset of the lichenoid type. The average time of taking the drug prior to the onset in my group of lichenoid cases, some 75 consecutive cases, was about five and a half months. Other workers have reported anywhere from two to six months as their average. It should be kept in mind also that cutaneous reactions to this drug antedated World War II and occurred in civilians. Holton and Winchester in 1938 reported a severe case of exfoliative dermatitis, presumably due to quinacrine hydrochloride. I believe this was the first case reported in the United States. That a contact dermatitis may occur was demonstrated by Dr. George Andrews before the New York Dermatological Society in 1943 with a case of a chemist exposed to quinacrine dust. Since that time contact sensitivity has, as Dr. Nisbet stated, been repeatedly demonstrated, both in the production of the drug and by patch testing a number of workers in both branches of the armed services. In a group of cases observed by Dr. Moon of Letterman General Hospital, during an eighteen month period, 9 patients with lichenoid dermatitis died. In 7 of these the cause of death was aplastic anemia. During the same eighteen months, only a total of 9 cases of aplastic anemia were seen at Letterman General Hospital. On the other hand, in this group of cases it was impossible to demonstrate any definite connection with hepatic damage during the same period of time.

Dr. Frederick G. Novy Jr., Oakland, Calif.: Dr. Nisbet has given us an excellent discussion of the various forms of eruptions produced by the ingestion of quinacrine hydrochloride. The hypertrophic form is so spectacular that diagnosis clinically is not hard to make. The eczematoid type, in my opinion, is nearly impossible to diagnose clinically. While I was in the Navy, a number of cases of eczematoid dermatitis occurred in the tropics among the personnel who had been aboard ship or who were in some nonmalarious area, where they were not getting this drug. Clinically it was impossible to differentiate these cases. I think they can only be diagnosed when one has a positive history and in addition exacerbate the eruption by giving the drug. During the middle part of the war, this disease was called the New Guinea disease. The reason it was seen in New Guinea in such high incidence was because there was a large concentration of troops that had been there for a long time and the "atabrine" discipline was very strict. The result was the appearance of many cases of this eruption in that area. Since then other cases have been reported from various surrounding islands. There have been cases, as Dr. Nisbet mentioned, from the Mediterranean theater, India and elsewhere. As the war progressed, we began to see patients who had gone directly to the Philippines in whom the eruption developed while there. Toward the end of the war, the patients were seen who had gone directly from the United States to Okinawa, which is 26 degrees north and out of the tropics. So I feel that the climate and environment of New Guinea itself did not play a role in the production of this spectacular and unusual disease. My experience has been the same as that of Drs. Drake and Nisbet in regard to exacerbations of the lesions in patients. These eruptions do not exacerbate with just the administration of one or two tablets of quinacrine hydrochloride. The eczematoid type usually takes six or seven days or a little longer to develop, and a hypertrophic type usually takes considerably longer than does the eczematoid.

Commander E. E. Barksdale, Bethesda, Md.: When investigation of this problem was first ordered at Bethesda it was called New Guinea lichen planus. It was possible to reproduce the condition in Washington, D. C. It is admitted that the climate in Washington is probably worse than it is in New Guinea. But this is a definite quinacrine-caused dermatitis. When 200 cases for investigation were requested after the Surgeon General had ordered the investigation, in only 38 of the 200 cases was it possible to prove true dermatitis caused by this drug, and that was from the entire Navy and Marine Corps in the Pacific. My impression is that it is a rare disease. Seventeen patients were selected to be put back on a regimen of quinacrine hydrochloride; in 16 of the 17 it was possible to reproduce the disease. In the other patient, administration of the drug was discontinued because of nausea and vomiting. I think it is a fixed type of drug eruption due to quinacrine hydrochloride.

Dr. Marvin Knoll, Los Angeles: I have seen this form of dermatitis from Milne Bay in New Guinea up through the Philippines and on the island of Honshu at Kure, Osaka and Kobe. All the patients gave a history of previous medication with quinacrine hydrochloride. Dr. T. Tanimura, professor of dermatology at the Imperial University in Osaka, told me he had not encountered a like condition among the Japanese troops. In Papua, New Guinea, from January 1944 until July 1945, a similar dermatitis was not seen in hospitalized or well natives. Among American service men and women the variety of cases ranged from small split-pea-sized individual lesions to the severe universal exfoliative dermatitis complicated by blood dyscrasias. Atabrine contains the acridine nucleus, a photosensitizing radical, and I believe many of these cases had their early beginning as a result of the sensitization of the skin to sunlight.

Dr. Alfred Hollander, Springfield, Mass.: Several months ago I saw a case which differs somewhat from the cases reported by the physicians who were in New Guinea. This patient while in the Pacific had taken quinacrine hydrochloride for thirty months up to November 1945 without any ill effects. He returned to this country in December 1945; he was first in the south, and he came back to Massachusetts in March 1946, when he had his first attack of malaria. He was again given quinacrine hydrochloride for about ten days. About three days after the discontinuance of the drug he had a yellow discoloration of the entire skin surface. I saw him about a week later, at which time he still showed the yellow discoloration and, furthermore, two slightly papular lesions the size of a nickel in the region of the right elbow. I told him to report back if he should see any further outbreak. He did not return until four weeks later, when he exhibited a lichen-planus-like eruption on various parts of his body, which I could not differentiate from any outbreak of typical lichen planus. In regard to Dr. Knoll's remarks, in Massachusetts there were cases of dermatitis due to this drug at Fort Devens in 1944. I think these cases with pigmentary changes should be compared with the cases Riehl of Vienna described at the end of World War I and which are called Riehl's melanosis. At that time it was a nutritional factor which brought out the disease. I believe that in dermatitis due to quinacrine hydrochloride a nutritional factor together with the climate and the sensitivity to the drug produces the pigmentary changes.

RHEUMATIC BRAIN DISEASE

Late Sequel of Rheumatic Fever

WALTER L. BRUETSCH, M.D.
Indianapolis

In recent years attention has been directed to the occurrence of rheumatic obliterating arteritis in the brain of persons with rheumatic heart disease.[1] This late cerebral sequel of rheumatic fever involves mainly the small meningeal and cortical vessels, producing gross or microscopic softenings in the cortex. Less frequently, larger vessels are affected. The involvement of the brain may occur from several months to many years after the acute stage of rheumatic fever, at a time when the person is otherwise enjoying good physical health. To this hitherto unrecognized cerebral process the term rheumatic brain disease was given. Similar cases have since been described in this country[2] and abroad.[3]

Although the frequency with which widespread and clinically manifest arteritis takes place in the brain of persons with rheumatic cardiovalvular disease is not yet known, its occurrence is by no means rare. It has been estimated from necropsy experience that approximately 5 per cent of the patients of the average mental hospital are afflicted with a combined rheumatic brain disease and rheumatic heart disease.

In 85 per cent of these patients the sedimentation rate was found to be accelerated. Correlative histologic studies disclosed rheumatic activity on the valves of the heart and in the cerebral and other vessels, indicating the presence of subclinical rheumatic fever in the absence of other symptoms which are generally regarded as manifesting activity.[1]

REPORT OF CASE

History and Course.—A woman patient aged 49 had four slight strokes, which were followed by a change in personality. After the last cerebral vascular accident, which affected her speech, she became destructive and uncontrollable.

The past history mentioned a leakage of the heart, which was discovered at the age of 20. There was no definite history of rheumatic fever in childhood. When the patient was 35 years of age, she had been in bed for several months with sciatic rheumatism.

Physical examination revealed a diastolic murmur at the apex. The pulse was irregular both in time and force. Its volume was small. The rate was 80 per minute. The blood pressure was 115 systolic and 90 diastolic. The roentgenogram and the electrocardiogram were indicative of mitral stenosis. An impediment of speech and hyperactive patellar reflexes were the only neurologic abnormalities. Mentally, the patient exhibited a considerable degree of deterioration. Pneumoencephalography showed dilatation of the right lateral ventricle. There was an increased amount of cortical air over both hemispheres. The widening of the subarachnoid spaces was particularly well defined in the region of the right sylvian point.

The Wassermann reaction of the blood and spinal fluid was negative. The cell count, total protein determination and colloidal gold curve of the spinal fluid were normal. Urinalysis revealed a trace of albumin and granular casts. There was an increased rate of sedimentation on several occasions, oscillating between 18 and 22 per hour (Cutler vein method). The temperature was normal. The blood count was as follows: hemoglobin 72 per cent; red cells 3,800,000; leukocytes 8,950. The differential count indicated a shift to the left.

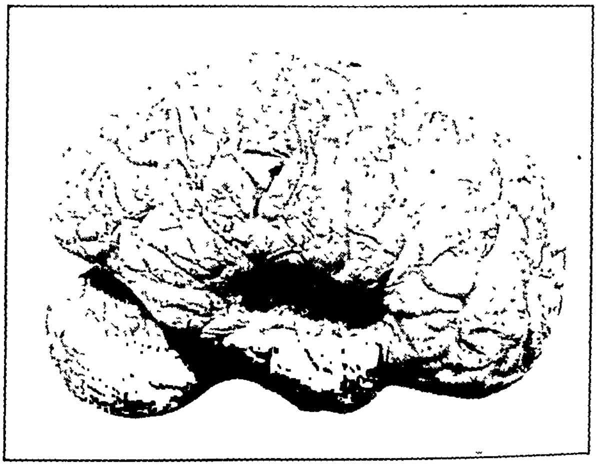

Fig. 1.—Rheumatic brain disease. Cortical infarction in right temporal lobe due to rheumatic obliterating arteritis.

The following diagnoses were made: psychosis with rheumatic brain disease; mitral stenosis, and subclinical rheumatic fever. The patient remained in the institution for four years. At no time was there any sign of congestive heart failure. She died suddenly from a pulmonary infarct.

Postmortem Observations.—Necropsy revealed rheumatic mitral stenosis. The mitral valve was thickened in its entire circumference. The chordae tendineae were shortened. Aschoff bodies were not found in the cardiac muscle, but isolated Aschoff cells were scattered throughout the myocardial interstitium. It has been said that Aschoff nodules are present only in about 11 per cent of rheumatic patients who die in the later decades of life.[4]

The lungs revealed recent rheumatic vascular disease accompanied by red infarcts. Numerous Masson bodies, which are considered the equivalent of Aschoff bodies in the heart, were observed in the pneumonic tissue.[5] In both kidneys were old

infarctions, which could be traced to rheumatic obliterating endarteritis of renal vessels.[6]

In the right temporal lobe (fig 1) of the brain was a large area of cortical softening, which extended into the anterior limb of the internal capsule. Smaller infarctions were present in the central and parietal cortex of both sides Extensive histologic search detected occluded meningeal vessels, which were responsible for the cortical softenings The rheumatic vascular obliterations extended over short segments only and for this reason could easily have been missed unless serial sections were made In addition to the gross infarcts there were present in the gray matter of all lobes microscopic areas of incomplete softening (acellular areas) In the vessels of the brain not a single yellow plaque was noted, excluding arteriosclerosis as the cause of the cerebral changes

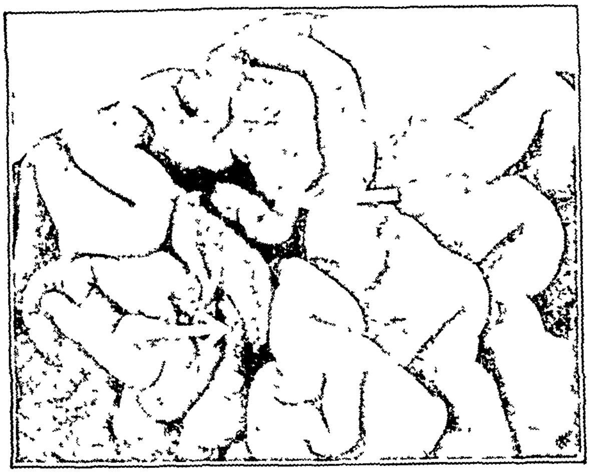

Fig 2—Softening and granular atrophy of convolutions in rheumatic brain disease

In the spinal cord were minor rheumatic alterations, consisting of incomplete vascular occlusions without softenings There were also a few vessels which were surrounded by lymphocytes These lesions, however, were not sufficient to produce such clinical symptoms of myelitis as were observed by Mørch Christensen in the wake of rheumatic fever[7]

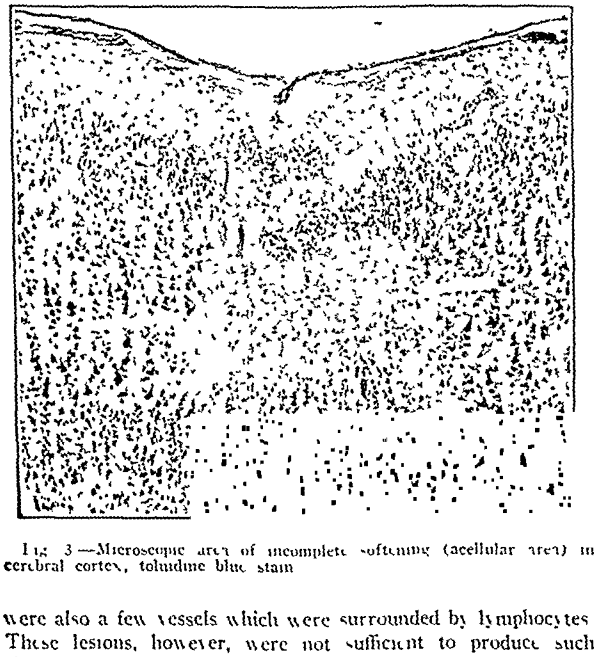

Fig 3—Microscopic area of incomplete softening (acellular area) in cerebral cortex, toluidine blue stain

COMMENT

This patient with rheumatic mitral stenosis, while in other respects in good health, experienced at the age of 49 a rheumatic involvement of the brain in the form of a diffuse obliterating process of the cerebral vessels. Similar vascular changes were observed in the kidneys. Furthermore, rheumatic fever was still or was again active in the lungs of this patient, as evidenced by Masson bodies and an increased rate of sedimentation, although the initial infection must have taken place several decades earlier. The disease history in this case exemplifies the validity of the newer concept which looks on rheumatic fever as a generalized process, involving various organs by way of the vascular system and being a continuous infection which lasts throughout life in some persons.

SYMPTOMATOLOGY OF RHEUMATIC BRAIN DISEASE

Rheumatic disease of isolated larger vessels of the central nervous system may produce various obscure neurologic conditions, which have puzzled the older neurologists. Leyden[8] in 1877 reported the sudden development of bulbar palsy in a woman aged 52, who at the age of 22 had had an acute form of rheumatic fever. There was mitral stenosis and a small area of fresh softening in the medulla oblongata Vascular occlusions in patients with rheumatic endocarditis have in the past been interpreted as always being caused by the detachment of emboli from the cardiac valves In the vast majority of patients, however, such occlusions, in the absence of auricular fibrillation, are the result of local proliferation of the intima.

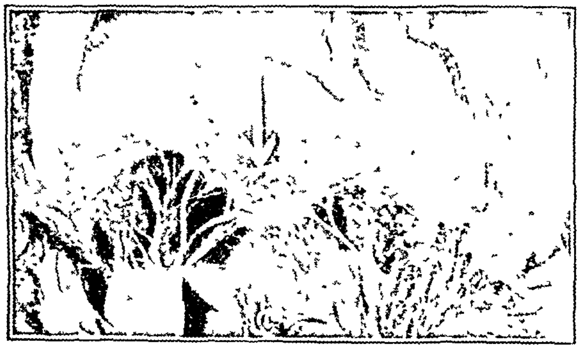

Fig. 4—Mitral valve with recurrent rheumatic endocarditis There is a large verruca on the closing border To the right is a continuous but barely visible layer of verrucous tissue

In general, rheumatic endarteritis has a predilection for the smaller vessels and in the brain involves frequently only the small meningeal and cortical branches, resulting in microscopic areas of softening in the gray matter. The ensuing mental disturbance is determined by the personality and by the age at which the cerebral involvement occurs. If the rheumatic infection causes cerebral damage in childhood, aberrations ranging from mild behavior disorders to slight mental deficiency states may result. In the young adult psychopathologic pictures suggesting dementia precox have been observed. Although the active rheumatic state is generally regarded as a disease of childhood, the late vascular lesions of rheumatic fever are not infrequently seen in middle life and even in the aged, being responsible for psychoses characteristic of that period. This is in accordance with the more recently emphasized observation that in many adult cases of rheumatic heart disease an active infection persists, usually in a manner so mild as to be scarcely detectable.[9]

RHEUMATIC BRAIN DISEASE AS A FACTOR IN THE CAUSATION OF SOME CASES OF DEMENTIA PRECOX

The studies on rheumatic brain disease have unearthed the fact that at necropsy 9 per cent of patients with dementia precox showed signs of rheumatic infection involving the brain as well as the cardiac valves.[1]

Modern psychiatry has viewed dementia precox and mental disease in general as a mere maladjustment of the person to social, environmental and emotional situations. The mass experiments which tested the so-called dynamic theories of psychiatry were the experiences of the two world wars. In environmental or emotional stresses were the cause of disabling mental illness, there would have been a decided increase of dementia precox and of other psychoses during the two wars. This was not the case.[10]

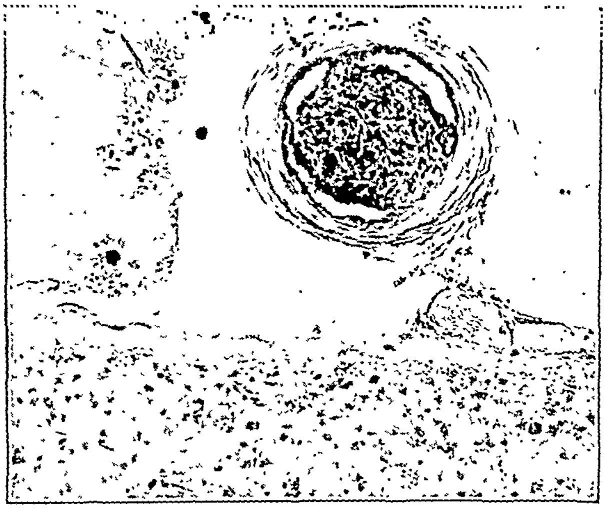

Fig. 5.—Rheumatic obliterating endarteritis of small meningeal artery. Proliferated intimal cells fill the lumen of the vessel. In the underlying cortex the ganglion cells have disappeared or show signs of degeneration; toluidine blue stain.

At various times the view has been expressed by Wagner-Jauregg,[11] Bleuler,[12] Singer[13] and others[14] that dementia precox does not represent an etiologic entity but is a clinical syndrome capable of subdivisions.

It seems as if the description of rheumatic brain disease, which occurs in 9 per cent of schizophrenic patients, is the first successful attempt to break down the dementia precox group into subgroups with definite etiologies.[1]

A few cases in which this cerebral sequel of rheumatic fever produced the symptomatology of dementia precox will be described.

A woman at the age of 35 began to hear voices which threatened her life. Later she had periods during which she became combative and violent. Except for a history of antecedent rheumatic fever, little was known about her life. She died after eleven years of institutional confinement in a state of advanced dementia. In the brain were gross (fig. 2) and microscopic (fig. 3) infarctions, which were due to rheumatic endarteritis of meningeal and cortical vessels. There were many old vascular occlusions, pointing out that one was not dealing with a terminal process. The clue to the exact nature of the cerebral involvement was furnished by the mitral valve, which disclosed chronic rheumatic endocarditis (fig. 4).

The history of another patient is revealing.

The woman patient, aged 37, was admitted to the Central State Hospital in 1890, coming from another institution where she had been an inmate since the age of 25. The diagnosis on admission was, according to the classification then in use, chronic mania. In 1915 the diagnosis was changed to dementia precox, and in 1925 the more modern term of schizophrenia was attached to the patient. When she died, examination of the brain and organs brought to light the true reason why this *patient had spent the greater part of her life in a mental institution.* In the brain was widespread rheumatic endarteritis (fig. 5) of many years' standing, associated with numerous microscopic areas of incomplete softening. In the kidneys were the residue of old rheumatic infarcts. The mitral valve divulged rheumatic alterations.

It may be interjected here that the rheumatic cerebral damage in these patients was not the anatomic substratum of the psychosis but was only an incidental and unrelated observation. The same inference could be made in regard to psychoses with vascular neurosyphilis. However, few clinicians doubt that the syphilitic obliterations of the blood vessels with their resulting cortical necroses constitute the basis of the mental disorder and are not merely terminal lesions.

Furthermore, the rare opportunity had presented itself to examine the brain of a schizophrenic patient with rheumatic endocarditis, who five months after the onset of the psychosis committed suicide. Here the same changes characteristic of rheumatic brain disease were present.

DIFFERENTIAL DIAGNOSIS BETWEEN RHEUMATIC BRAIN DISEASE AND CEREBRAL LESIONS IN THROMBOANGIITIS OBLITERANS (BUERGER'S DISEASE)

An increasing number of cases with cerebral involvement in thromboangiitis obliterans (Buerger's disease) is being reported.[15] In some of these patients,[16] however, endocarditic changes on the cardiac valves have been present, implying that the vascular alterations represented rheumatic arteritis and not thromboangiitis obliterans. It is obvious, then, that a diagnosis of Buerger's disease in the presence of rheumatic cardiovalvular disease should be made with caution. Even the histologic differentiation between thromboangiitis obliterans and rheumatic vascular disease is at times most difficult.[17] A general criterion is that Buerger's disease involves particularly the larger arteries, while rheumatic fever has a preference for the smaller vessels.

CONCLUSIONS

About 5 per cent of the patients in mental hospitals have a combined rheumatic brain disease and rheumatic heart disease. The ratio between rheumatic men and women is 1:3.

The sedimentation rate was accelerated in 85 per cent of these patients, suggesting the presence of subclinical rheumatic fever.

The cerebral involvement consisted of a rheumatic obliterating endarteritis with subsequent areas of softening. To this process the term rheumatic brain disease was given.

ABSTRACT OF DISCUSSION

DR. FREDERICK P. MOERSCH, Rochester, Minn.: Dr. Bruetsch has added another chapter to his many studies on the involvement of the nervous system associated with rheumatic heart disease. That cases of fatal rheumatic heart disease reveal definite pathologic findings in the brain has also been substantiated by other investigators. As a result of all these studies there is no longer any good reason to doubt the close relation between rheumatic heart disease and the many neurologic disorders that accompany it. That cerebral lesions of rheumatic origin may produce mental symptoms seems a reasonable deduction. Here the correlation between the pathologic observations and the clinical symptoms is not as clear as it is in the cases of a neurologic nature. Unfortunately it is not known how numerous or how extensive lesions in the brain must be for the production of mental symptoms. It is known that senile plaques may be found in the brain without any apparent associated mental symptoms; however, if the number of plaques is extensive there are the mental symptoms of Alzheimer's disease or senile dementia. In 1939 Dr. Kernohan and his associates (*Arch. Neurol. & Psychiat.* **42**:789-809 [Nov.] 1939), in a study of the "Involvement of the Nervous System Associated with Endocarditis," found neuropathologic changes similar to those noted by Dr. Bruetsch. In 23 of their 42 cases there was rheumatic endocarditis with fatal outcome. In 21 of these 23 there were neuropsychiatric disorders, and in 5 there was evidence of psychosis. In spite of these observations it remains a fact that from a clinical point of view mental symptoms are seldom observed in patients with rheumatic heart disease. Many patients are seen who have rheumatic heart disease; they are seen repeatedly and in various stages of their illness, but it is rare indeed to find any unusual mental symptoms which one might attribute to rheumatic brain damage. To my knowledge, no extensive psychiatric study has been carried out in patients suffering from rheumatic heart disease. Certainly such a clinical study seems indicated, as undoubtedly more careful psychiatric surveys would probably indicate a much greater incidence of psychiatric symptoms than is now appreciated.

DR. NATHAN MALAMUD, San Francisco: Dr. Bruetsch has for a number of years drawn attention to his observations of rheumatic brain disease in a variety of neurologic and psychiatric disorders. There is one aspect of this problem which I would like to discuss, namely, the value of such studies in conditions which are usually dismissed as being functional, particularly in schizophrenia. In this disorder organic cerebral changes are denied, but, as Dr. Bruetsch has emphasized, investigation in routine state hospital autopsies might disclose subgroups in which an organic process is undeniable. The vascular disease reported by Dr. Bruetsch probably forms one of these subgroups. There is another in which a similar mechanism, though of different etiology, might play a role. This concerns some patients with catatonic schizophrenia in whom, at the height of an acute attack, signs of vasomotor instability, convulsions and other organic symptoms develop, with fatal termination. In such cases the observations at necropsy are invariably negative. However, careful microscopic investigation of the brain shows signs of impaired cerebral circulation but without evidence of any vascular disease or occlusion. Two cases will serve as illustrations. A catatonic form of schizophrenia of about one and a half years' duration in a woman aged 20 ended abruptly in an episode of stupor, convulsions and hyperthermia which lasted three days, pathologically showing extensive infarction of the cerebral cortex in the presence of normal blood vessels. In the cortex of this patient there were numerous acellular areas and small infarcts at an early stage, but the meningeal and cortical vessels themselves were normal and not occluded. In the second case recurrent catatonic attacks over a number of years in a man aged 24 terminated in an episode of stupor associated with hyperthermia, bradycardia and apnea and pathologically showed widespread changes of the cortex without any vascular lesions. In this second case there was distinct paling of the cortex in some areas, particularly the troughs of the convolutions by contrast with the crests. On higher magnification there was widespread ischemic degeneration of the ganglion cells. It may be significant that the same mechanism of disturbed cerebral circulation is suggested in these so-called functional disorders as in the cases of rheumatic brain disease. I should like to ask Dr. Bruetsch whether he has any explanation for the occurrence of schizophrenic, epileptic or other types of disorder in the different cases he reported, in spite of apparently similar pathologic conditions in the brain.

DR. N. W. WINKELMAN, Philadelphia: The late Dr. John Eckel of Buffalo and I reported in 1932 a group of 5 cases from a great number of similar cases from the Philadelphia General Hospital, in which the brain of the patient was involved in acute rheumatic fever. To this condition we gave the name of nonsuppurative encephalitis rheumatica. From our study we concluded that acute rheumatic fever does not produce a specific change in the brain that can be recognized either grossly or microscopically. Second, the changes that are present in the brain of patients who have shown neurologic and psychiatric symptoms during the course of acute rheumatic fever are similar in every way to the changes that occur in any other acute infections and toxemias. We considered that edema of the brain played a part in the production of the acute manifestations. We found an endarteritis of the small vessels similar to that described in syphilis by Nissl and Alzheimer, which we felt might be the result either of a mechanical process, the edema, or of a toxic reaction through the blood stream. At that time we found the same acellular areas in the acute cases that Dr. Bruetsch observed in his chronic cases, but I must add also that we found the same areas absolutely indistinguishable from those of rheumatic fever patients with other infections and toxemias. We felt that the occurrence of endarteritis completely changed the picture in the brain. We found so-called brain purpura, hemorrhagic encephalitis, in a great many of our cases of endarteritis. I would like to ask Dr. Bruetsch first, if he has found similar pathologic changes in patients with histories of other infectious processes and second, whether he believes the endarteritis itself is responsible for the changes that he has described in the brain.

DR. J. M. NIELSEN, Los Angeles: Does Dr. Bruetsch think that the actual picture of dementia precox or schizophrenia is ever produced by these rheumatic lesions, inasmuch as dementia precox begins with a loss of interest and attention, seclusiveness and so on, followed only much later by symptoms referable to the cortex? I do not see how any type of pathologic anatomy in the cortex or subcortex can ever explain the entire syndrome of dementia precox. There are many symptoms in dementia precox that are referable to the diencephalon, the thick subcutaneous tissue, the oiliness of the skin, the general unhealthy appearance of the patient in general and a certain peculiar pathologic plantar response which is not a Babinski. Things of that sort characterize dementia precox, and it seems to me that they are not simulated exactly by any other condition of the brain.

Fahr, T.: Die rheumatische Granulomatose (rheumatisches Fieber, Rheumatismus infectiosus specificus, Rheumatismus verus) vom Standpunkt des Morphologen, Ergebn. d. inn. Med. u. Kinderh. **54**:357, 1938.

Dr. Leopold Hofstatter, St. Louis: Dr. Bruetsch's paper is an important contribution toward a better understanding of schizophrenic reactions in relation to physical illness. In a number of brains from schizophrenic patients he could show cortical changes that he identified as late sequels of rheumatic fever. The significance of the pathologic conditions described for the etiology of schizophrenic reactions will have to be evaluated in the light of similar observations in mentally healthy persons. The fact that personality features often are a determining factor in the final outcome of physical illness may have some bearing on the matter. From Dunbar's pertinent studies it is known that rheumatic fever in the repressed, passive and submissive person usually results in a well-established, irreparable pathologic process (rheumatic heart disease) whereas the more spontaneous and aggressive patient recovers without permanent (cardiac) damage. The occurrence of organic changes of the brain as sequels of rheumatic fever in schizophrenics may therefore be explained on psychosomatic grounds.

Dr. Walter L. Bruetsch, Indianapolis: I want to answer first the question of Dr. Moersch, who mentioned that there are many patients with rheumatic heart disease who do not manifest mental symptoms. In this connection there is an analogy with syphilis. There are many instances of syphilis, but in only a few patients does there develop vascular neurosyphilis (syphilitic endarteritis) associated with mental symptoms. Dr. Malamud portrayed the cerebral changes of patients whose disease was diagnosed during life as dementia precox, emphasizing the point, which also was the theme of my paper, that in some cases of dementia precox there are demonstrable organic lesions. Dr. Winkelman brought up the question whether the vascular alterations are specific for rheumatic fever. I am inclined to the statement that the etiology of obliterating endarteritis at times cannot be diagnosed from the morphologic appearance of the lesion alone. Various conditions lead to endarteritis, among them syphilis, thromboangiitis obliterans and rheumatic fever. In the study with which this paper is concerned only cases which also involved rheumatic endocarditis were considered. This established with certainty the rheumatic etiology of the vascular process. For some time internal medicine has recognized endarteritis due to rheumatic fever. It has been shown to occur in almost every organ of the body. Finally, the cerebral vessels have been added. Dr. Winkelman in 1929 published a number of instances with proliferative endarteritis of varied causation, and in 1 of these cases the vascular occlusions were obviously due to rheumatic fever. As to the question whether the symptoms of dementia precox could be caused by the cerebral changes which were observed in these patients, no single localization or type of cerebral process is recognized which will produce the symptomatology of dementia precox. This possibly answers to some extent Dr. Nielsen's question. In general one may say, however, that a diffuse involvement of the cerebral cortex is one of the various possibilities which can initiate schizophrenic symptoms. The description of rheumatic brain disease directs attention to a hitherto unrecognized phase of rheumatic fever. This has led to concern among persons with a history of rheumatic fever and among parents whose children have this disease. There is, however, a note of optimism. Even if the brain should become involved in later years, rheumatic encephalopathy has a fairly high rate of spontaneous recovery. The recovery may occur even though gross or microscopic cerebral lesions have occurred. This may be explained by the fact that after the acute vascular process in the cerebral vessels has subsided, there remains enough normal brain tissue for the patient to continue mental processes. In some instances recovery has been speeded by intensive salicylate therapy.

Clinical Notes, Suggestions and New Instruments

GRANULOCYTOPENIA DUE PROBABLY TO "PYRIBENZAMINE"

WYNDHAM B. BLANTON, M.D.
and
M. E. B. OWENS Jr., M.D.
Richmond, Va.

Granulocytopenia is believed not to have been described hitherto among the untoward side effects of tripelennamine hydrochloride, "pyribenzamine" (N. N. R.) (N′pyridyl-N′ benzyl-N-dimethylethylenediamine hydrochloride), therapy.

REPORT OF CASE

A widow aged 73, whose general health had always been excellent, was first seen in 1942 for a vulvovaginitis. She was again seen on Sept. 23, 1946 for an urticaria of seven weeks' duration. Put on a dosage of 200 mg. of "pyribenzamine" daily, she showed an immediate improvement of symptoms. She was hospitalized on Oct. 10, 1946 for environmental and dietary trials. The etiology of the urticaria was not determined by the initial or subsequent investigations. The patient was discharged on Oct. 29, 1946 with the urticarial outbreaks improved but continuing. At this time examination of her blood revealed a count of 5,700 leukocytes, with a differential of polymorphonuclear neutrophils 74 per cent; lymphocytes 22 per cent, and monocytes 4 per cent. The dose of "pyribenzamine" was reduced to 150 mg. daily, and its administration was continued. Chloral hydrate 0.6 Gm. was given nightly. Senna leaf infusion, self-prepared, completed the list of drugs she was taking at this time, except for nicotinic acid, 100 mg. daily from November 18 to 20. (Subsequently, when the blood count had returned to normal, nicotinic acid was again given without effect on the leukocyte picture.)

Hemoglobin 75% (12.8 Gm.); red blood cells 4,400,000; platelets 246,000; reticulocytes 0.6%.

The patient was again hospitalized on Nov. 23, 1946. She had not felt well for a week. An elevation of the temperature to 102 F. had occurred three days before admission. Two days before, a slight, nonproductive cough had developed. On the morning of admission the temperature was 103 F., and bouts of chilliness were experienced. Slight nausea and a dull headache were complained of, but there was no soreness of the throat. Apart from the fever, the physical examination was noncontributory. The chest was clear. No ulceration or inflammation of the mouth or throat was present. A superficial ulcer on the left labium majus, recurrent for years, was healing. Blood culture and routine urinalysis were negative. The blood count was: leukocytes 1,300; polymorphonuclear neutrophils 3 per cent; lymphocytes 92 per cent; monocytes 5 per cent; erythrocytes 4,400,000; hemoglobin 75 per cent (12.8 Gm.); platelets

---

From the Allergy Service, Medical College of Virginia.

246,000; reticulocytes 0.6 per cent. "Pyribenzamine" therapy was discontinued immediately. Treatment with penicillin, 50,000 units intramuscularly every three hours, was instituted on admission. This was reduced next day to a dosage of 25,000 units every three hours until November 29, at which time it was discontinued. The temperature returned to normal the day after admission and remained so. The attendant symptoms also responded immediately. Chloral hydrate was continued in doses of 0.6 Gm. four times a day until November 29. Senna leaf infusion was given nightly throughout the hospital stay. Twelve cubic centimeters of a concentrated liver extract intramuscularly, with 40 mg. of folic acid by mouth, were given daily from November 30 to December 9. Slight, occasional outbreaks of urticaria were treated by the injection of a solution of epinephrine subcutaneously.

Scratch tests to "pyribenzamine" in solution were negative. Following the method of Leftwich,[1] direct intradermal tests with serum from another patient being given the drug were negative. Attempts were made to demonstrate leukocyte sensitivity to "pyribenzamine" by in vitro lysis of leukocytes by the method of Squier and Lee.[2] A 0.01 per cent solution of the drug in isotonic solution of sodium chloride was added in equal parts to the heparinized blood of the patient and to controls. Serial white counts at intervals during two hours were suggestive, but not conclusive, of the destructive action of "pyribenzamine" on the patient's leukocytes in vitro. It was considered inadvisable to test the patient directly by the readministration of the drug.

SUMMARY

Fever and a marked depression of granulocytes in the peripheral blood, developed in a woman aged 73 after eight weeks of tripelennamine hydrochloride, "pyribenzamine" (N. N. R.), therapy in moderate doses for chronic urticaria. After withdrawal of the drug and the intramuscular use of penicillin, the temperature dropped to normal in twelve hours. The total leukocyte count and the differential percentage returned to normal in twelve days. The neutropenia is thought to have been the result of the drug.

Council on Foods and Nutrition

PLAN FOR ACCEPTANCE OF JUICES

In order to encourage the production of fruit juices containing high natural levels of vitamin C, the Council accepts orange juice in which at least 40 mg. of ascorbic acid per hundred cubic centimeters of juice is conserved.

The following product meets the standards and rules established by the Council for fruit juices.

Attention is called to the fact that this product, while packed in a hermetically sealed container, is not heat treated and should be consumed promptly after defrosting. If it is not to be used immediately after defrosting, it may be kept under refrigeration of approximately 35 degrees F. in the unopened container for three or four days. James R. Wilson, M.D., *Secretary.*

FRUIT JUICE—ORANGE JUICE

Birtcher Brothers and Dorr, Inc., Glendora, Calif.

Glen-Dora Quick Frozen California Orange Juice.

Analysis (submitted by manufacturer).—Total solids 14.43%, moisture 85.57%, ash 0.40%, fat (ether extract) 0.06%, protein (N × 6.25) 0.56%, crude fiber 0.01%, carbohydrates other than crude fiber (by difference) 13.40%.

Calories.—0.55 per gram; 15.62 per ounce.

Vitamin Content.—	Mg. per 100 Cc.
Ascorbic acid	
In juice	43.2
In fruit (before processing)	43.8

Council on Physical Medicine

REPORT OF THE COUNCIL

The Council on Physical Medicine has authorized publication of the following report.

The Council wishes to express its appreciation for the valuable cooperation of the Consultants on Electrocardiographs in reviewing this report. The consultants are Drs. A. R. Barnes, George Fahr, Harold E. B. Pardee, William D. Stroud, Carl J. Wiggers and Frank N. Wilson. Howard A. Carter, *Secretary.*

MINIMUM REQUIREMENTS FOR ACCEPTABLE ELECTROCARDIOGRAPHS

1. The electrocardiographs shall be equipped with a suitable recording mechanism.

2. The recorded response of the instrument to externally applied square wave voltages shall be adjustable to a sensitivity of 1 cm. per millivolt when this voltage is applied to the leads of the instrument through a series resistance of 2,000 ohms. This sensitivity shall be maintained without further adjustment within ± 5 per cent for a period of thirty minutes under operating conditions. Operating conditions for the purpose of this requirement are defined as (1) for alternating current operated instruments as line voltages varying from 105 to 130 volts at frequencies within ± 2 per cent of the specified value for the instrument, (2) for battery operation as one or more of the batteries operating at 80 per cent of the rated life or voltage whichever condition occurs first. Under these conditions the response of the instrument to its incorporated standardizing signal of 1 millivolt shall be within ± 5 per cent of the response to the externally applied test signal. The instrument shall incorporate means of superimposing its intrinsic test signal into the cardiographic tracing as recorded from any lead position. It should be possible to maintain this test signal voltage for a period of two or more seconds.

3. The amplitude response of the instrument to 1 millivolt peak sinusoidal voltage variation up to 15 cycles per second shall not fall below 90 per cent, and up to 40 cycles shall not fall below 50 per cent of the square wave response to equivalent voltage variations. The amplitude response of the instrument to 1 millivolt peak sinusoidal voltage variation up to 300 cycles per second shall not exceed 100 per cent of the square response to equivalent voltage variations.

4. The response of the instrument at 0.2 second after the application of a direct current of 1.0 millivolt shall not deviate more than ± 10 per cent from the response at 0.04 second. The test voltage of 1 millivolt should be applied to the leads of the instrument through a series resistance of 2,000 ohms.

5. When the instrument is adjusted to the sensitivity specified in requirement 2 the recorded response shall be directly proportional to the applied voltage (direct current) within ± 5 per cent over a range of 2 cm. on either side of zero.

6. With the two input terminals connected together, a potential difference applied between them and ground should not produce a deflection of more than 1 per cent of that produced by the same potential difference applied between the two input terminals.

7. The instrument shall incorporate a means of continuously recording time intervals on the record. These intervals shall be of one second duration or less and shall be accurate within ± 2 per cent. A means of superimposing this time signal on the electrocardiographic tracing at the operator's will will be accepted as fulfilling this requirement. It should be possible to record the time signal for a period of at least two seconds. Recording paper preruled so as to indicate time intervals, assuming a constant paper speed, shall not be construed as fulfilling this requirement.

8. The construction of the instrument shall be such as to meet the shock hazard requirements of the Underwriters' Laboratories, Inc.

9. Instruments shall be submitted and considered according to the Official Rules of the Council on Physical Medicine.

10. The standards of merchandising and the acceptability of advertising shall meet the Rules of the Council on Physical Medicine.

SATURDAY, MAY 31, 1947

CENTENNIAL SESSION

As The Journal goes to press with this Centennial Number, arrangements have been completed for the largest and most comprehensive session of the American Medical Association ever held. Over 10,000 physicians have already indicated their intention to be present. Rooms have been assigned to all of those who have applied. The Local Committee on Arrangements in Atlantic City, headed by Dr. David B. Allman, announces that additional rooms are available in excellent hotels in the suburbs of Atlantic City. Regular bus service will be provided without charge from these hotels to the Boardwalk. Any one who wishes to attend the annual session should not hesitate to come because of lack of suitable accommodations. The hotel committee, under Dr. Robert A. Bradley, 16 Central Pier, Atlantic City, N. J., will do everything possible to secure satisfactory accommodations for any Fellow of the American Medical Association who wishes to participate in this notable event.

Elsewhere in this issue of The Journal are examples of telegrams, letters, resolutions and editorials that have been published in various periodicals and sent directly to the headquarters of the Association, some in connection with the actual birth date of the Association, May 5. Information is available that many periodicals with large national circulation will also have special issues to commemorate the occasion.

National broadcasts are scheduled for practically every day of the week beginning Sunday, June 8, at which time the speakers at the religious service, Monsignor Fulton J. Sheen, Dr. Joshua Loth Liebman and Dr. Ralph Cooper Hutchison, will be presented at 11 a. m., Eastern daylight saving time.

The Journal has noted previously the issuing by the Post Office Department of a stamp commemorative of the Centennial. The third assistant postmaster general, Mr. Joseph Lawler, is coming to Atlantic City in person to present a sheet of the stamps to the House of Delegates. The J. B. Lippincott Company has arranged to issue a special envelop with a cachet or device commemorative of the occasion and carrying one of the new stamps, so that every physician in attendance may have some to mail to his home.

"The History of the American Medical Association" is in the bindery, and the W. B. Saunders Company, which is the publisher, announces that the book will be available in Atlantic City.

The exhibits, including both the Scientific and the Technical, are most comprehensive, and practically all exhibitors have entered into the spirit of the occasion. Many of these exhibits will be devoted to the history of the advancement of medical science. Others will include mementos of the Centennial for the physicians who visit the exhibits.

The distinguished foreign guests constitute an amazing list representative of medicine throughout the world. Other notables in attendance will include the surgeons general of the various services, Secretary of War Robert P. Patterson, Assistant Secretary of the Navy for Air John Nicholas Brown and possibly also the Secretary of the Interior, Julius A. Krug.

Attention should be called again to the fact that the opening general meeting will be held in the large auditorium on Tuesday evening, June 10. The Philadelphia Festival Orchestra under Alexander Hilsberg will give a concert, which will begin at 7:45. The meeting itself will begin at 9 o'clock. Seated on the stage will be the officers and the Past Presidents of the American Medical Association, the distinguished representatives of the Medical Society of New Jersey and of Atlantic County, and the foreign guests who will be presented on this occasion. This meeting is open both to the medical profession and to the public. Arrangements can be made for seating more than 5,000 people. However, Fellows of the Association who wish to attend should arrive not later than 7:30 so that all may be properly seated before the concert begins.

Two excellent orchestras, those of Tommy Tucker and Eddie Lane, have been secured to supply the music for the President's Reception on Thursday night, June 12. Because of the number of distinguished persons in attendance, there will be three receiving lines. The reception will begin promptly at 9 o'clock. This will also be held in the large hall of the Atlantic City auditorium.

The scientific program for this session of the Association has been especially designed to commemorate one hundred years of medical progress. Each of the sections has a special contribution by a leader in the specialty concerned, and there is to be a special session on the history of medicine.

The celebration of the Centennial has been carefully planned and has required attention to detail beyond any similar occasion in the history of the Association. Every physician who can possibly be present should endeavor to come to the session, if not for the entire week, at least for one day, in order that he may look back in the years to come with pride of personal participation in this celebration.

DIETARY TREATMENT OF HYPERTENSIVE DISEASE

Shortly after the beginning of the twentieth century Achard and Loeper [1] and Widal and Lemierre [2] demonstrated that a diet of low salt content was helpful in hypertensive disease. Allen in 1920 also proposed a salt free diet for hypertension, but his studies and conclusions did not receive general acceptance by the medical profession.

The possibilities of treating hypertensive disease and its complications by dietary methods has become the subject of renewed study. Among such investigations are those of Grollman and his colleagues,[3] Selye,[4] Wheeler and his co-workers [5] and Kempner.[6] Grollman and his co-workers found that the blood pressure of rats with experimental renal hypertension could be lowered by administering diets in which the sodium content had been decreased by dialysis. Only 6 cases were reported, the reduction of pressure being to normal levels in 2, moderate reduction in 3 and no decline at all in 1. The radical reduction of sodium in the food employed by these investigators cannot be readily duplicated.

Selye, working with experimental animals, found that low sodium and low protein diets would prevent the nephrosclerosis and hypertension which could be produced in these animals by corticotrophen, desoxycorticosterone and other salt active corticoid hormones. In a small number of human beings with rapidly progressive hypertensive disease similar dietary measures were considered effective. Selye believes that the low content of protein and sodium in some of the diets which have been empirically proposed for the treatment of hypertensive disease is the basis of the resultant favorable reports, such as the so-called rice diet for hypertension studied by Kempner.

The volume of experimental and clinical studies and the scientific standards of many of them would seem to confirm the view that a diet low in sodium is helpful for a high percentage of patients with hypertensive disease. Indeed, Wheeler and his co-workers believe that the use of a diet low in sodium in the presence of congestive failure of the heart is also based on sound experimental and clinical grounds. Not all patients of this type will respond. These investigators found that patients with congestive failure due to coronary or hypertensive heart disease responded much better than those in whom rheumatic heart disease was the cause of the failure.

Further work on this therapeutic approach is needed. *In spite of the overwhelming evidence of value of a* special dietary regimen, agreement on specific constituents of the diet and the indications and contraindications has not been obtained. Careful clinical observations under controlled conditions are necessary before the dietary regimen can be considered worthy of general adoption in clinical practice.

DIAGNOSTIC MEDICAL CARE AND COMMERCIAL LABORATORIES

Accurate diagnosis is the cornerstone of modern medical care. Following adequate review of the patient's history and complete physical examination supplemental clinical laboratory and x-ray examinations may be necessary in many cases. The physician determines, following these additional diagnostic studies, whether or not still further tests, such as functional and neuropsychiatric tests, bronchoscopy and gastroscopy, are required in a much smaller number of cases. Diagnostic medical examinations which involve pathologic and radiologic investigations and clinical laboratory studies may be done in doctors' offices and in hospitals. Fundamental to any examination is the availability of trained personnel that it may be conducted properly and interpreted adequately. In the larger centers, radiologists and pathologists (qualified physicians) usually conduct these examinations. In smaller communities, circumstances often require that they be performed by general practitioners who have had some supplemental training in radiology or pathology.

The profound importance of competent pathologic examination is evidenced in the early diagnosis of malignant disease. Consider the woman with a lump in her breast or the youth with a painful lesion involving bone. In either case carcinoma may be present. If it is, the swiftest method of cure is removal of the breast or leg. On the decision of the pathologist in most instances this grave step must be taken. If there is a well trained pathologist accessible to the hospital or physician's office the patient is likely to receive a correct diagnosis so that a life saving measure is then justifiably undertaken. If, however, reliance is placed on a poorly trained or unqualified person needless and mutilating operations may be performed for benign tumors. If a diagnostic procedure such as a simple blood count or a roentgenographic study of the chest is performed by competent personnel under the supervision of and responsible to a specialist in one of those fields, the end result is likely to be earlier diagnosis and better medicine. An incompetent, untrustworthy test is often worse than none!

In the early days of clinical laboratory and roentgenologic medicine technicians (notably after World War I) sometimes offered their services as practitioners in these fields. Many were moderately experienced. Owing to the shortage of trained medical specialists, these technicians were frequently accepted and supported by the medical profession. In the meantime, departments of radiology and clinical pathology were becoming established in medical schools, and young physicians were being encouraged by the faculties to enter these fields. Today the continued development of such competent specialists may well depend on the extent to which commercial laboratories, supervised, owned or controlled by nonmedical personnel, are eliminated from the field.

In some parts of the country the commercial laboratory has become synonymous with convenient diagnoses and even rebates. To the credit of the medical profession such practices are exceptional. Nevertheless the signs are clear. Physicians must support medical laboratories which meet the standards of the Council on Medical Education and Hospitals, owned and conducted by medical men trained in their fields. There should be no place in medicine for commercial nonmedical interests that exploit both patient and physician and undertake without recognized responsibility decisions that can rest safely only on those licensed to practice medicine and specially qualified in their fields.

Current Comment

LATE RESIDUALS OF INFECTIOUS HEPATITIS

An estimated 90 to 95 per cent of patients with acute infectious hepatitis appear to recover entirely within a period of two to three months. Klatskin and Rappaport[1] have attempted to determine the incidence of residuals in a large group of patients presumably recovered from this disease. The studied group consisted of 217 persons presumably cured of infectious hepatitis, of whom 47 had symptoms, 59 had an enlarged liver and 41 had evidence of impaired liver function—a total of 108, eliminating duplications, or about 50 per cent of the cases. The significant symptoms were right upper quadrant pain and fat intolerance. Structural changes were not established, though the evidence suggests that the residuals mentioned indicate a disturbance of the liver. Good health and full activity over long periods—the time varying from two months to twenty-seven years—were compatible with these changes. The severity of the jaundice at the time of the disease was the only symptom which appeared to play a significant part in the incidence of residual changes. Evidence could not be deduced from the patients studied that the residuals described predispose the liver to further injury. Likewise the presence of late residuals of infectious hepatitis did not appear to reflect any tendency to develop cirrhosis, though coarse nodular cirrhosis occasionally occurs during the first six months of chronic progressive or recurrent infectious hepatitis.

TENNESSEE AND THE NATUROPATHS

In 1943 and 1945 the general assembly of Tennessee passed a law legalizing the licensing of naturopaths. A naturopathic board was established to deal with such licensure. Now by an act of the last general assembly in Tennessee the naturopathic board has become extinct. Within a week after the law was first passed a member of the naturopathic board sent a letter to naturopathic healers through the nation telling them that Tennessee had now become the happy hunting ground for their profession. The publication of the Tennessee Department of Public Health states that a horde of naturopathic healers met at the Maxwell House in Nashville four months later and hundreds of licenses were issued like tickets to a banquet. A reporter for the *Commercial Appeal* estimated that about 1,500 Tennessee licenses to practice naturopathy were doled out to those able to purchase them; evidence was developed indicating the establishment of a political organization for the maintenance of this unfortunate system of practice. Among other naturopaths who migrated to Tennessee was William E. Estep, who has a long list of bogus performances and fake licenses to his credit. The Memphis newspaper gives an amazing account of a visit by one of its reporters, Harry Woodbury, to Estep's clinic. When the reporter entered he was greeted by a man sitting behind a plain desk who said to him "You look like you are in quite a bit of pain. What seems to be troubling you, sir?" The reporter submitted to an examination by Estep during which the naturopath said to him "You are eaten up with sinus!" He was also told by Estep that he had stomach ulcers and that his blood pressure was dangerously high. A previous examination had shown that the reporter was not actually subject to any of these maladies. The naturopath gave Mr. Woodbury an electrical treatment and three prescriptions, one of which called for 4 ounces of sulfocyanate. Estep was indicted for practicing medicine without a license and sentenced to a fine of $500 and imprisonment in the county workhouse for eleven months and twenty-nine days. The Tennessee incident is reminiscent of the diploma and license scandals of a previous generation. It calls to mind the shipping of carloads of physicians with well nigh worthless diplomas from schools in St. Louis and Kansas City to Connecticut and Arkansas, where conveniently eclectic boards licensed them. That was the scandal that gave the United States such notorious charlatans as Brinkley and Schireson. Who knows how long Tennessee and the rest of the United States will be paying for the folly of the general assemblies of 1943 and 1945?

ORGANIZATION SECTION

CONGRATULATIONS AND GREETINGS

Note.—Here are examples of congratulatory messages, editorials and letters received in the headquarters office in association with the Centennial of the Association.—Ed.

A. M. A. FOUNDERS

(The Evening Star, Washington, D. C., May 13, 1947)

Emerson's doctrine that a great institution is "the lengthened shadow of one man" is subject to amendment in certain cases. The American Medical Association, now celebrating the centennial of its establishment, was the result of a matching of the minds of a number of men of distinction. It grew from two conventions, held at New York and at Philadelphia in May 1846 and May 1847. The constitution in its current form declares: "The object of this Association shall be to promote the science and art of medicine. Contributing to this end, the association shall endeavor to unite into one compact organization the medical profession of the United States for the purpose of fostering the growth and diffusion of medical knowledge, of promoting friendly intercourse among American physicians, of safeguarding the material interests of the medical profession, of elevating the standard of medical education, of securing the enactment and enforcement of just medical laws, of enlightening and directing public opinion in regard to the broad problems of hygiene and of representing to the world the practical accomplishment of scientific medicine."

Foremost among the primary sponsors of the ideals thus set forth was Dr. Nathan Smith Davis, who as early as 1843 proposed such a movement. His major interest was in the better training of medical practitioners—a concern which was shared by the celebrated psychiatrist Dr. Pliny Earle and by the chairman of both of the preliminary conventions, Dr. Jonathan Knight. All three of these founders were possessed of a genius for persuading people of different views to work together.

Another generation than that of the original organizers produced Dr. Nathaniel McCormack of Kentucky, who, with the assistance of several colleagues, revised the constitution of the Association and drafted the prevailing plan for the management and conduct of its affairs. He too deserves to be remembered in connection with the centenary celebration.

MEDICAL CENTENARY

(New York Times, May 7, 1947)

On May 5, 1847 some 250 delegates representing more than forty medical societies and twenty-eight colleges met at Philadelphia to form what has ever since been the American Medical Association. A century later the Association has 131,590 members and 72,243 Fellows. No other body wields greater professional influence. During the long decades when the government was indifferent to the quality of food and drugs and the "patent" medicine man was in his heyday, the Association was a bulwark of protection. Quacks were pursued, educational standards were raised, drugs were appraised, hospitals and schools were approved or disapproved, a dozen first class medical publications, of which THE JOURNAL is the best known, were made indispensable purveyors of knowledge, nostrums were exposed as the frauds that they were, fads were riddled.

For all these blessings the public has reason to be grateful. With some of the economic and social policies of the Association we have disagreed. But certainly in intelligence, in education, in breadth of culture the Association is not surpassed by any other organization, because no other so carefully excludes from its ranks the badly trained, the charlatans and the sectarians. We wish it another century of usefulness.

* * * *

HOSPITALS AND THE A. M. A.

(Hospital Management, May 1947)

In the leading article the writer states that "hospitals may well share the pride of the Association in the completion of its hundred eventful years, for the history of the American Medical Association, and of the medical profession in general, is irrevocably linked with the history of hospitals. The two have worked as a smooth-running team, complementing and supplementing each other's activities with the same broad objective in mind: the betterment of the health of mankind."

* * * *

CENTENARY OF THE ASSOCIATION

(Good Housekeeping, June 1947)

In Atlantic City in June the American Medical Association will observe its Centenary, and so it is appropriate that we extend to the Association our sincerest congratulations and good wishes. It is doubtful whether any other organization has had as much of an influence for good on American life. Organized medicine in this country is powerful, as it deserves to be and must be. But for the highly centralized headquarters in Chicago we would not now be so free of quacks, and of bad medical legislation, and of medical plans and schemes that take advantage of a gullible public. Immeasurable good has come from the American Medical Association. Largely because of it the status of medicine in America is unexcelled; the stature of the profession is the highest ever known. We salute the Association; and, in honoring it, we honor a group of indispensable citizens.

A. M. A. CENTENNIAL

(Drug Trade News, May 19, 1947)

The news that the American Medical Association reached its one hundredth birthday on May 5 is alone sufficient to spotlight its profoundly valuable contributions to the advancement of medicine and the general welfare.

Whatever the field of medical interest, be it education, hospital development, public health administration, research, expansion of medical care, drug control, journalism, a study of its history will show that the A. M. A. has always been the dominant voice demanding ever higher standards and ever greater public benefits.

From the outset, the A. M. A. became dedicated to the task of progressively improving medical education, and so effectively did it achieve that today medical education in the United States is by all odds vastly superior to that in any other section of the world.

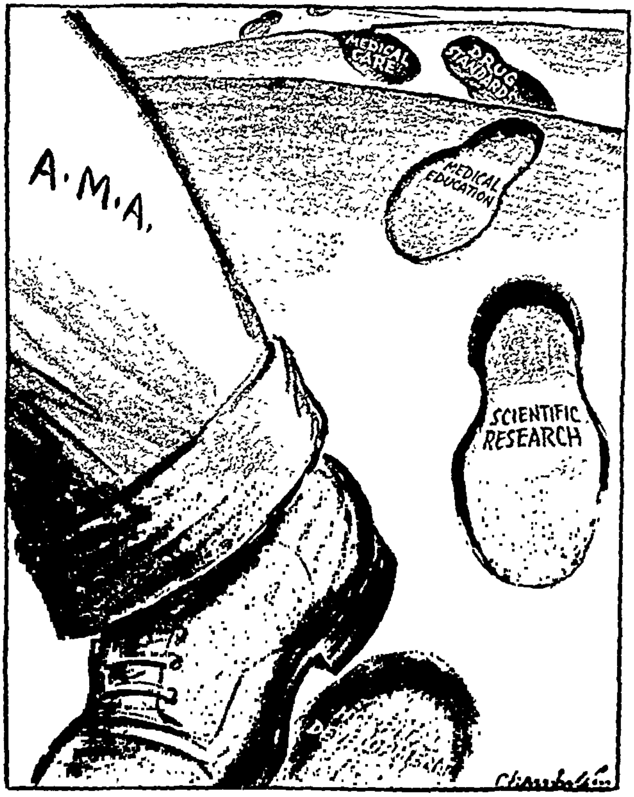
In the field of drug standardization, control and promotion, the A. M. A. has, through its Council on Pharmacy and Chemistry, been a most constructive influence in behalf of greater scientific accuracy and more dependable therapeutic agents. Here its leadership, which necessarily includes the element of discipline, may well be said to have instituted new concepts of pharmaceutical integrity.

The A. M. A. has been the strong, motivating factor underlying medical research. It has fostered the establishment of research departments and laboratories in the medical schools, in various governmental services and in the great pharmaceutical industry plants. The high standards of scientific effort which now obtain in so many areas of medical care are a tribute to the A. M. A. conviction that science and medicine are partners in the cause of human betterment.

Quite properly, we think, the A. M. A. has fought the many half-baked, visionary schemes, plans and plots to socialize the medical profession. While it seems inevitable that, in due course, the government must play a greater hand in the expansion of medical care, the hold-back policy of the A. M. A. has assured a more careful appraisal of the problems and more practical programs for meeting them.

By every test, the A. M. A. has gloriously justified its first hundred years.

GIANT FOOT PRINTS



Published in *Drug Trade News*, May 19, 1947.

CENTURY OF PROGRESS

(Boston Post, April 30, 1947)

On May 5 the American Medical Association will be 100 years old. It has had a century of growth that is truly phenomenal. Starting with a bare handful of physicians, today its rolls include 131,590 members and 72,243 Fellows. Its accomplishments in the field of public health too have been notable. Always in the forefront in the prodigious advancement of medical science during that period, it well deserves national recognition at this first major milestone for the fine job it has done.

THE DOCTOR

(The Lion, May 1947)

Next month the American Medical Association will celebrate its Centennial, it being just one hundred years ago that that organization, so great in accomplishment and rich in service to humanity, was founded in Philadelphia. At that time the medical profession was still in an exceedingly primitive state, the practitioners being for the most part men with little knowledge of the human body and much less of the cause and nature of disease, and who in treatment relied largely on blood letting, nostrums and superstition. There were no professional standards and no medical ethics. Yet there were here and there a few enlightened physicians and surgeons who recognized their responsibilities and followed the higher ideals of their calling, and it was a group of these men who in 1847 banded together into an association for the primary purpose of elevating medical education, promoting research and establishing the standards and principles of ethics so sorely needed for public protection.

The contrast between medicine as it was studied and practiced in 1847 with medical education and practice of today is so vast as to represent one of the greatest marvels of modern times. During the forthcoming Centennial it is but fitting that special honors will be paid that vast body of physicians, surgeons and specialists in the various branches of medical science who during these hundred years have developed the remarkable diagnosis, treatment and surgical technics that have conquered many of the diseases that formerly scourged mankind, that have brought miraculous cures to untold millions of sufferers and that have increased the span of life by many years.

But the spotlight will specially fall during this Centennial on that kindly friend and benefactor of humanity, the Family Doctor. Maybe he is unknown to the world at large. Maybe he is spending his life in relative obscurity, ministering to the ailing, the sick and distressed of his own neighborhood, or in a small town or rural community. But in the history of medicine, as in the hearts and minds of his neighbors and townsmen, he is a man of greatness nevertheless. For it is the Family Doctor who is the core of his profession. Not only has all medical knowledge sprung from the experiences of his practice, but he is the medium through whom the century's medical progress is made a reality for us all. And, in thinking of the Family Doctor as the consecrated and faithful servant of humanity, we recall the dramatic characterization of him presented by the famous painting "The Doctor," which is reproduced on the front cover of this issue of the *Lion*. It is the masterpiece of Sir Luke Fildes, which hangs in the Tate Gallery in London and which was exhibited in the Hall of Science at the Century of Progress Exposition in Chicago in 1933-1934. Not only is the painting itself dramatic, but the story behind it is equally so.

Nearly sixty years ago Queen Victoria of England arrived at one of her rural estates to find one of her servant women and her husband grief stricken because their only child lay at the point of death. The Queen immediately telegraphed to London for her personal physician, Sir James Clark. He arrived by special train and remained in constant attendance on the child until the crisis was past and she was well on the way to recovery. The girl was literally snatched from the grip of death, and Queen Victoria was so impressed with this medical miracle that she commanded Sir Luke to place on canvas the scene in the humble cottage as the child's life was feebly flickering, as a tribute to the entire medical profession for its devotion to the cause of humanity.

Lionism prides itself on the many thousands of men of medicine within its ranks, in all of its eighteen countries. Ever since the founding of Lions International three decades ago, medical men have been among the most active Lions Club members. They have been tireless workers not only in their own professions but in every Lions Club activity for the welfare of their city or town and area, and the number of them who have occupied high posts in Lionism is countless.

Lionism also prides itself on the fact that, just as the medical profession has cooperated intensely in the growth and development of our Lions Club and Association, so has it been privileged to cooperate with the medical profession in a great many ways. Lions clubs in all our eighteen countries have sponsored and very often financed the construction of numerous hospitals, clinics and special wards, have equipped them with laboratories, diagnosis and surgical equipment, furnishings and facilities of every kind. They have served communities lacking adequate medical services by locating competent doctors in them, have built blood banks, have assisted in spreading public health education, have promoted modern sanitation—to mention only a few such activities.

Lionism, in a word, could never have been the great constructive force in public service that it is today were it not for this mutual cooperation by and with the men of medicine, and Lions everywhere salute them on this Centennial of their first professional organization.

Melvin Jones.

ONE HUNDRED YEARS OF PROGRESS

(Grand Rapids, Mich., Herald, May 10, 1947)

Medical science as it is known today has made its greatest advancements in the last hundred years. It may indeed be said to have been the product of the last century.

And it is more than coincidence that this great period should have been the period of the American Medical Association, founded May 5, 1847 and now celebrating its centennial.

In this country, the A. M. A. has taken the lead in elevating the standards of medical education and practice, in the elimination of "quacks" and "quack" medicines, in promoting research and in improving the public health.

Countless comparisons might be made between the methods and knowledge and standards of today and those of a century ago. They are not necessary. Most of us in our lifetime have seen the results of progress in too many lines of medical practice to need comparisons with the crude ways and sparse facts of a hundred years ago.

One by one, and in large measure due to the organization that now numbers 131,590 of America's 190,000 doctors of medicine in its membership, we have seen the passing of fads and frauds and the introduction of new skills and new drugs.

Nor have the art and science of medicine reached the end of progress. Its practitioners will go on and on, finding new and newer means of alleviating suffering and saving lives and making life more worth living.

NOTABLE CENTENNIALS

(Northwest Medicine, May 1947)

It should be known by every physician that the Atlantic City meeting of the American Medical Association in June will celebrate its one hundredth anniversary. Whether such an occasion distinguishes an individual or an organization, it is one of the most notable occasions that can be observed Whatever distinction is thus conveyed to our national medical association, it is merit and honor for the accomplishments of this organization for the benefit of the medical profession of this country and the welfare of its population. Undoubtedly a record attendance will be recorded at this meeting, and the official registration of the first day will be crowded and confused. Fortunately, if one desires to take advantage of this privilege, one can obtain from Dr. Lull, Secretary of the Association, a questionnaire which may be filled in advance and save the time and trouble of registration at the meeting.

Another notable centennial celebration is that of the New York Academy of Medicine which has served the medical profession and citizens of New York City for one hundred years. It has maintained the highest standard of service with constant accomplishments for the public health, providing medical information as well as instruction. Its greatest activity is through its magnificent reference library in one of the city's outstanding edifices on Fifth Avenue and 101st Street. This is one of the largest and most unusual medical libraries of the nation. The New York Academy of Medicine is to be congratulated for its conspicuous and successful career during the past century.

(TELEGRAMS)

From the Medical and Chirurgical Faculty of Maryland:

The Medical and Chirurgical Faculty of Maryland extends hearty congratulations to the American Medical Association on its one hundredth birthday May 5th 1947 and best wishes for a most successful meeting on June ninth to thirteenth when you take recognition of this anniversary.

W. Houston Toulson, M.D., Secretary.

* * * *

From the Tristate Hospital Assembly:

Six thousand members of the Tristate Hospital Assembly opening their seventeenth annual meeting today at the Palmer House send heartiest congratulations to the American Medical Association on its one hundredth anniversary.

Malcolm T. MacEachern, M.D., Chairman.

* * * *

From the Chicago Convention Bureau:

The Chicago Convention Bureau extends its congratulations to the American Medical Association on its one hundredth anniversary. Your accomplishments have shown you to be one of the outstanding organizations of the world and we offer our best wishes for your continued growth and success.

I. S. Anoff,
President, The Chicago Convention Bureau.

* * * *

From the American Protestant Hospital Association:

The American Protestant Hospital Association Extends Congratulations on your Century of Service and Education.

Albert G. Hahn, Executive Secretary.

* * * *

From Belgium:

Bruxelles Medical Association sends best wishes for your centenary.

(LETTERS)

From the Rho Pi Phi Pharmaceutical Fraternity:

Rho Pi Phi Pharmaceutical Fraternity salutes the American Medical Association upon its "century of progress." May the future find the A. M. A. in the front ranks of the march toward the advancement of the Public Health in America.

A Happy and Healthy Birthday.

Very truly yours,
Maurice Goldsmith.

* * * *

From the National Social Welfare Assembly, Inc.:

May I extend the greetings and hearty congratulations of the National Social Welfare Assembly to the American Medical Association and its great membership on the occasion of your Association's one hundredth birthday.

The long and brilliant record of scientific and human care progress in the field of medicine and health that has grown out of the organized interest of the medical profession as expressed in the American Medical Association is one of the gratifying chapters in our American way of doing things. The people of this country owe much to this one hundred years of organized professional achievement.

The voluntary and government organizations affiliated with the National Social Welfare Assembly find many occasions for hearty and close partnership with your members in the furtherance of services of mutual interest. We therefore feel very much a part of your centenary observance. The days ahead will undoubtedly bring even closer associations between the medical profession and organized social welfare, for we are united in the great common purpose of the well being of people.

Sincerely yours,
Robert E. Bondy.

* * * *

From the Editor of the British Medical Journal:

The British Medical Association and the American Medical Association are almost contemporaries, there being only the small gap of fifteen years between the foundation of these two powerful professional organizations.

The American Medical Association is the force it is today because it was built on sound foundations. When the founders met in 1847 in Philadelphia, where the framers of the Constitution had met sixty years before, their first concern was with medical education and medical ethics. The American Medical Association was based on first principles, and during the hundred years that have elapsed everything else has been added to it.

English medicine may be proud that it played a part in your formation and development. Dr. Thomas Percival, F.R.S.—as Dr. Morris Fishbein points out in his "History of the American Medical Association"—formulated his principles of medical ethics, and these served as a model for the American medical profession.

The British Medical Association may boast too that it has shared in what is perhaps your most important development—the establishment of The Journal of the American Medical Association. It is many decades ago now that your Association invited to the United States Dr. Ernest Hart, then Editor of the *British Medical Journal,* to discuss plans for starting a similar journal, similarly linked with a voluntary association of medical men. And we may be proud too that the second Editor of The Journal was an Englishman by birth and an American by adoption—Dr. George H. Simmons, who did such pioneer work both for The Journal and for your Association.

The links between our two associations are close indeed. We look with admiration at the influence exerted by the American Medical Association on all aspects of professional life in the United States. As an editor I should like to pay my humble tribute to the magnificent standard of medical journalism set and maintained by The Journal and by the specialist journals published by the American Medical Association.

In a hundred years the American Medical Association has become what a contemporary medical historian rightly describes as "the largest and most powerful medical organization that the world has yet seen." On this centenary occasion we salute the memory of its founder, Nathan Smith Davis, and wish the Association *bon voyage* for its second hundred years.

Hugh Clegg, M.A., M.B., F.R.C.P.

* * * *

From the Philippine Medical Association:

Whereas, on June 9-13, 1947 the great American Medical Association will celebrate the 100th anniversary of its foundation;

Whereas, this great medical association has, during the century of its existence, been consistently useful and progressive;

Whereas, all the wonderful advances in medical education and in public health and sanitation in the great North American nation have been brought about largely through the patriotic and unselfish labors of this medical association with its important state ramifications; and most, if not all, of the medical legislations in the American continent have been made possible only through the harmonious collaboration between this association and the American government;

Whereas, the Philippines—from the first years of its association with the United States, throughout its existence as a Commonwealth, until now that it is a Republic—has, through the Philippine Islands Medical Association, which was at one time accredited as one of the state branches of the American Medical Association, been the grateful recipient of the many benefits of this association; and

Whereas, the American Medical Association, in its one hundred years of useful life, has consistently and painstakingly upheld and guarded the best physical and medical interests of the American people as well as those of the American medical profession in general; therefore be it

Resolved, That the Philippine Medical Association, conscious of its national debt of gratitude to the American Medical Association, hereby expresses its sincere congratulations to the American Medical Association on this auspicious date and conveys the best wishes of the medical profession of the Philippines for the continuance of the useful and vigorous life of its former mother, the American Medical Association.

Januario Estrada,
President.

From an address by Alphonse M. Schwitalla, S. J., Dean, St. Louis University School of Medicine, at annual banquet of the Illinois State Medical Society, May 13, 1947:

We are this year celebrating the hundredth anniversary of the foundation of the American Medical Association. It has been a century of leadership by medicine; leadership through the science of medicine; leadership through the practice of medicine, through the ethics of medicine, through medical education, through the thousand and one applications of medical thought to industry and commerce, to government and finance. It has been a century of challenged leadership because many were those who would not acquiesce in the leadership of medicine and who tried to place their own puny judgments of what is good for mankind in opposition to the combined judgment of medicine as personified in the reputable physicians who stood for competence and medical wisdom. No, I would not exaggerate; the leadership of medicine has not been perfect. There have been moments in a hundred years when lesser councils prevailed, when the bayleaves and olive branches of the first caduceus became the paired serpents and the wizard wand of the second caduceus; when in moments, that were fortunately very rare, the pressure of public opinion at times prevailed over principle; but all in all the triumph is really this, that after one hundred years of effort in medicine man can really look to medicine in America for leadership and find ever so much to attract his loyalty and his allegiance, to elicit his confidence, to inflame his enthusiasm, to command his acquiescent obedience. For medicine in America is a movement besides being a science and an art. It is a philosophy; it is public opinion; it is an enterprise; it is a national activity; it is a dynamic and an essential element in the American pattern; it is a pervasive phase of American psychology and sociology; it is a trend toward the truth, an urge toward morality. All of this man has found in medicine when he looks to medicine.

RESOLUTION PASSED BY THE SENATE OF PENNSYLVANIA

On May 5, the American Medical Association will celebrate its one-hundredth anniversary, having been founded in Philadelphia on May 5, 1847.

It was founded as an association of physicians "to promote the science and art of medicine; to elevate the standard of medical education and practice; to bring about the enactment of uniform legislation for the public welfare and to protect the public health."

In connection with its purpose to protect the public health, it has over the years helped initiate many legal actions and has helped to bring innumerable criminal prosecutions against quacks and quackery. The Association has also found itself involved as a defendant in many libel suits because where it has seen medical charlatans and others involved in introducing pseudo medical skullduggery into the field of medicine it has not hesitated to inform the public accordingly and to take those steps which it regarded as the quickest way to stop such practices.

The American Medical Association has during its many years been a constructive influence because of the caliber of the men who have been its officers and members; therefore be it

Resolved, That the Senate of the Commonwealth of Pennsylvania hereby wishes to join in commemorating the centennial celebration of the American Medical Association and to congratulate its officers and members and to extend to them its best wishes in carrying out its many plans for advancing the study and practice of medicine and for protecting our citizens from ill considered medical experiments and questionable drugs.

The Senate also expresses the hope that the American Medical Association at its centennial convention, to be held June 9th to 13th, will give great consideration to the problem of improving the general health of the average American citizen, mindful of the low standard of health which was discovered by our military authorities during the last war; and be it further

Resolved, That the Secretary of the Senate transmit a copy of this resolution to the President of the American Medical Association.

G. Harold Watkins, Secretary
Senate of Pennsylvania.

CENTENNIAL BROADCASTS FROM ATLANTIC CITY

The Bureau of Health Education announces the following broadcasts connected with the Centennial Celebration of the American Medical Association at Atlantic City:

Saturday, June 7. "Doctors—Then and Now," Nevada and Northern California, speaker Lawrence Parsons, M.D., representing Nevada and California Medical Associations; N. B. C. and affiliated stations, 4:30 to 5 p. m., Eastern Daylight Time.

Saturday, June 7. "Generations of Doctors" (tentative title), a fantasy story of the doctor of 1847 in contrast with his descendant, a doctor of 1947, dramatized with music; Columbia Broadcasting System and affiliated stations, 10:30 to 11 p. m., Eastern Daylight Time.

Sunday, June 8. Speakers from the Centennial religious observance, Msgr. Fulton J. Sheen, Rabbi Joshua Loth Liebman and Dr. Ralph C. Hutchison, President of Lafayette College; N. B. C. and affiliated stations, 11 to 11:30 a. m., Eastern Daylight Time.

Monday, June 9. Official opening of the Scientific Exhibit, Dr. Morris Fishbein, Editor of The Journal, and Dr. Harrison H. Shoulders, President of the American Medical Association; American Broadcasting System and affiliated stations, 4:15 to 4:30 p. m., Eastern Daylight Time.

Monday, June 9. "Stephen Graham, Family Doctor": this Mutual network broadcast, usually originating from New York, will be originated from the American Room at the Hotel Traymore as the entertainment feature for the annual dinner tendered the House of Delegates and officers of the American Medical Association by the local medical profession. The entire production will be moved from New York as a demonstration to the delegates and as a special event commemorating the Centennial of the American Medical Association. The topic will be "Medical Service in Rural Areas." The special script will be written by Willys Cooper and produced by Wynn Wright. The program is under the general supervision of Dr. W. W. Bauer and Harriet Hester.

Wednesday, June 11. Address by Dr. Edward L. Bortz: Columbia Broadcasting System, 6:15 to 6:30 p. m., Eastern Daylight Time. Topic: "Looking Forward from A. M. A. Centennial."

Friday, June 13.—Interview: Dr. Edward L. Bortz, President of the American Medical Association; interviewed by Harriet Hester, Mutual Broadcasting System and affiliated stations, 10:30 to 10:45 a. m., Eastern Daylight Time. Topic: "One Hundred Years of American Medicine."

Saturday, June 14. "Doctors—Then and Now"; closing program of the series entitled "American Medical Cavalcade," summarized by Dr. W. W. Bauer; N. B. C. and affiliated stations, 4:30 to 5 p. m., Eastern Daylight Time.

In addition to the Monday night Mutual broadcast of the "Stephen Graham, Family Doctor" show, the speeches by Dr. Fishbein and Shoulders on the American Broadcasting System, and the speeches of Dr. Bortz on the Columbia Broadcasting System and the Mutual Broadcasting System will originate from Atlantic City; "Doctors—Then and Now" on N. B. C. will originate both Saturdays from Chicago; "Generations of Doctors" on C. B. S. will originate from New York.

DISTINGUISHED GUESTS AND VISITORS

Dr. Hugh A. Clegg

Dr. Sven Forssman

Dr. John A. Pridham

Dr. Jose Valls

The accompanying pictures of guests from other countries to the Centennial Session are in addition to those published in The Journal, May 3

Dr. Hugh Anthony Clegg, editor of the *British Medical Journal;* general supervisor of the World Abstracting Service, which the British Medical Association started in January 1947; formerly house physician at St. Bartholomew's Hospital, London; assistant medical officer, London County Council; medical registrar, Charing Cross Hospital; author of "What Is Osteopathy?" (jointly), Wartime Health and Democracy; Medicine in Britain (British Council); revised Black's Medical Dictionary Dr. Clegg will attend the Centennial Session as a representative of the British Medical Association

Dr. Sven Forssman, professor and head of the department of industrial hygiene, National Institute of Public Health, Stockholm, Sweden; secretary of the Swedish Medical Society; editor of the *Scandinavian Journal of Hygiene;* vice chairman of the Swedish Association of Industrial Physicians; will address the Section on Preventive and Industrial Medicine and Public Health at the Centennial Session.

Dr. John A. Pridham, London, England, chairman, International Relations Committee of the British Medical Association; member of the Council and Insurance Acts Committee; member of the Royal College of Surgeons and of the Organization Committee of the World Medical Association; justice of the peace for Weymouth; author of "Problem of the Care of the Neurotic Patient."

Dr. Jose Valls, Buenos Aires, Argentina, professor of orthopedic surgery, University of Buenos Aires Medical School; president of the Argentina Medical Association and formerly president of the Argentina Society of Orthopedic Surgery; vice president, Section on Orthopedic Surgery, fourth congress of the Pan American Medical Association in 1933 and secretary of the eighth congress, in 1940; chief of orthopedic and traumatic surgery at the Durand Hospital; author of "Low Back Pain and Sciatica"; will address the Section on Orthopedic Surgery at the Centennial Session on "Aspiration Biopsy in the Diagnosis of the Lesions of the Vertebral Bodies."

Dr. Charles Hill, formerly deputy secretary and now secretary of the British Medical Association; formerly clinical assistant, Children's Department, London Hospital; London University Extension lecturer in biology, and formerly chairman, Central Council for Health Education; author of "What Is Osteopathy?" (jointly) and "Wise Eating in Wartime," will attend the Centennial Session as a representative of the British Medical Association.

Dr. Frank S. Patch, Montreal, Canada, for many years professor of urology and chairman of the departments of urology and surgery at McGill University; formerly president of the Canadian Medical Association and managing editor of its journal; formerly president of the Royal College of Physicians and Surgeons of Canada; president of the Montreal-Medical Chirurgical Society; colonel in the Canadian Army Medical Corps in World War I; author of numerous articles in the field of urology; will address the Section on Urology at the Centennial Session.

Dr. Andrew R. Hunter of the Manchester Royal Infirmary, Manchester, England; visiting anesthetist to the Thoracic Unit, Baguley Emergency Hospital; consultant anesthetist to Stepping Hill Hospital, Stockport; special anesthetist in the recent war in the Emergency Medical Service in Scotland; will address the Section on Anesthesiology at the Centennial Session

Dr. Harry Guy Dain, London, England, chairman of the council of the British Medical Association and of the negotiating committee of the medical profession concerned with national health service legislation; formerly the chairman of the Insurance Acts Committee and of the Representative Body of the B. M. A., will attend the Centennial Session as a representative of the British Medical Association.

Dr. Charles Hill

Dr. Frank S Patch

Dr. Andrew R. Hunter

Dr. Harry Guy Dain

NEW STAMP TO HONOR AMERICAN MEDICAL ASSOCIATION

(Published in The Columbus [Ohio] Citizen, April 13, 1947)

The United States Post Office Department will issue another commemorative stamp, honoring the doctors of America, it was announced this week by Postmaster General Robert E. Hannegan

The special stamp will be of the 3 cent denomination and will be placed on sale June 9, on the occasion of the one hundredth anniversary of the founding of the American Medical Association.

"In so honoring the American doctor," Mr. Hannegan said, "we are paying tribute to the men and women of medicine who devote their lives to the cause of humanity.

"The alleviation of pain and suffering and the betterment of mankind are their creed. The contribution which they have made to our national life is one of which all Americans can be proud and grateful."

Details as to the place of sale and a description of the stamp will be announced later, the department said

J. Charles Baxter.

Bureau of Information

LOCATION OF PHYSICIANS

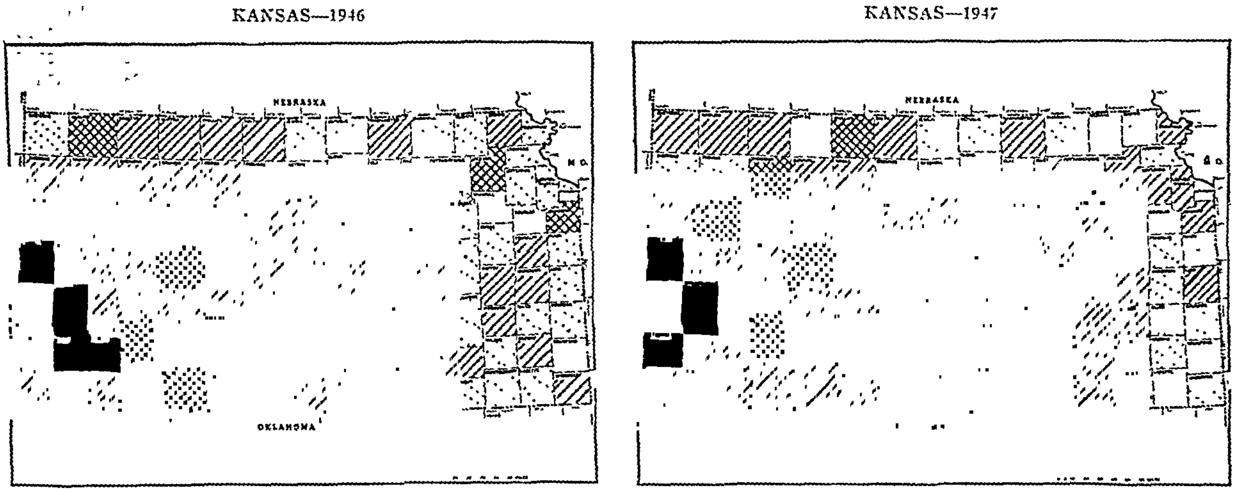
Virginia Shuler
Chicago

This is the second of a series of charts showing the trend in locations of physicians from April 1946 to January 1947; the first series appeared May 17, page 301.

"Upon the return of medical officers from the armed forces, the distribution of physicians in Kansas was greatly improved. Generally speaking, the larger communities in the state are adequately supplied with physicians at present. Requests are still being received from less populated areas, but these also are being filled.

"At present there are thirty or forty communities in Kansas that have requested a resident physician. In almost all instances those communities are near larger cities where medical care is available. Frequently these communities have less than 200 population and could not in themselves adequately support a doctor. There are, however, some areas where the physician-patient ratio is still below normal. There is one community in Kansas with a population of more than 1,000 that does not have a resident physician. Many of the smaller Kansas towns are contemplating the construction of hospitals. If these projects are completed, it appears that those communities will become more attractive to doctors and at that time the needs that exist today will gradually be filled."

MR. O. E. EBEL, Executive Secretary.
Kansas Medical Society,
512 New England Building,
Topeka, Kan.



Population, based on 1943 estimated Census figures, per active physician (excludes teaching, research, hospital administration, public health and state hospitals) by county.

"The distribution of physicians in Colorado is still too heavily concentrated in the large and medium size cities if the state is taken as a whole So long as the current general prosperity lasts I believe that cities such as Denver, Colorado Springs, Pueblo, Greeley, Fort Collins, Boulder and Grand Junction can adequately support the large number of physicians now practicing in these locations, but if a recession or a genuine depression sets in, as many economists predict, I feel that some or all of the cities named will find themselves overstaffed with physicians There still are fifteen or twenty excellent locations for general practitioners in the very small communities and rural areas of Colorado and probably another fifteen or twenty locations of this type which might be called good rather than excellent Three or four such communities might be considered in critical need Within the last six months many previously critical locations in Colorado have been filled, indicating somehow that a better appreciation of the worth of rural practice has developed among some physicians Financial consideration seems to have little or no bearing on failure of physicians to fill the remaining critical locations in Colorado; rather, failure of physicians to accept these locations is due to lack of hospital facilities and lack of good general living conditions With the increased interest of local communities in developing hospital facilities, with or without the aid of Public Law 725 (Hill-Burton Hospital Survey and Construction Act), I consider the Colorado situation hopeful for filling remaining critical areas within the next year"

MR HARVEY T. SETHMAN, Executive Secretary,
Colorado State Medical Society,
537 Republic Building,
Denver 2.

Washington Letter

(From a Special Correspondent)

May 29, 1947.

General Bradley Opposes Giving Free Automobiles to Amputee Veterans

Gen. Omar Bradley, Veterans Administrator, has registered a protest with Chairman Edith Nourse Rogers of the House Veterans Committee opposing legislation to give free automobiles to veterans who lost their sight or suffered arm amputations during the war. He warned that, "by logical progression, such a move might ultimately demand that all seriously disabled veterans be supplied with automobiles, in addition to compensation and other benefits." He estimated the cost of giving cars to all amputees and blind veterans at $21,930,000. Congress has already appropriated $30,000,000 for a program under which leg amputees now get cars at government expense provided they cost no more than $1,600. War amputees demonstrated new artificial limbs for President Truman, Secretary of War Patterson and General Bradley.

International Council of Nurses Holds Precongress Meeting

Delegates to the ninth congress of the International Council of Nurses in Atlantic City, May 11 to 16, met first in Washington, where they attended a tea at the White House as guests of Mrs. Truman and conducted business sessions. More than 5,000 nurses from thirty-two countries, 500 of them from overseas, will be at the congress. Speakers declared that the nursing profession is "only at the threshold of its potential value to the good health of the world tomorrow." Delegates also observed the one hundred and twenty-seventh anniversary of the birth of Florence Nightingale (May 12, 1820), founder of modern nursing.

Interracial Medical Forum Held in National Capital

Described as the first interracial medical program of its kind ever held in Washington, a postgraduate medical assembly was conducted under sponsorship of the District of Columbia Physicians Forum to discuss "Problems of the Aging Patient." Dr. Ernst Boas, assistant clinical professor of medicine at Columbia University, was chairman. Speakers included Drs. W. Montague Cobb and Charles Drew of Howard University Medical School, Benjamin I. Weininger, president of the Washington-Baltimore Psychoanalytic Society, Charles Geschikter, professor of pathology at Georgetown University Medical School, and Frederick Zeman, director of the Home for Aged and Infirm Hebrews, New York.

Dr. John Minor Heads District Medical Society

Dr. John Minor, specialist in internal medicine, was elected president of the District of Columbia Medical Society, succeeding Dr. Raymond T. Holden. Other officers elected were William P. Herbst Jr. to the executive board, Iva A. Pelzman first vice president, Carolyn Pincok second vice president, W. Ross Morris and William W. Chase to the board of censors, Coursen B. Conklin delegate to the American Medical Association and Worth B. Daniels and J. Lawn Thompson Jr. alternate delegates to the American Medical Association.

Navy Consents to Use of Observatory Land for Medical Center

The Navy Department revealed that it is willing to move the Naval Observatory, between Wisconsin and Massachusetts avenues, to a new site to make way for the proposed new $20,000,000, 1,500 bed medical center planned for the nation's capital. The new center would incorporate three local hospitals, Garfield, Emergency and Episcopal. The last Congress authorized an appropriation of $35,000,000 for the overall project.

Modern Medicine in the Treatment of Alcoholism

Dr. Howard W. Haggard, Yale physiologist, informed the Washington Committee for Education on Alcoholism that modern medical methods are already successful in the treatment of alcoholic addicts. He said that 80 per cent of those who continue through the full period of treatment at the Yale clinic recover. Dr. Haggard spoke on "Alcoholism as a Medical Problem."

Coming Medical Meetings

American Medical Association, Atlantic City, June 9-13. Dr. George Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Aero Medical Association of the United States, Atlantic City, Ritz-Carlt Hotel, June 4-6. Dr. David S. Brachman, 1016 Dime Bldg., Detroit 2 Secretary.

American Association for the Surgery of Trauma, Atlantic City, Hot Claridge, June 5-7. Dr. Gordon M. Morrison, 520 Commonweal Ave., Boston 15, Secretary.

American Association of Genito-Urinary Surgeons, Absecon, N. J., Ju 4-6. Dr. Charles C. Higgins, 2020 E. 93d St., Cleveland 6, Secreta

American College of Allergists, Atlantic City, Hotel Senator, June 6 Dr. Fred W. Wittich, 401 LaSalle Medical Bldg., Minneapolis 2, Se retary.

American College of Chest Physicians, Atlantic City, Ambassador Hot June 5-8. Mr. Murray Kornfeld, 500 N. Dearborn St., Chicago 1 Executive Secretary.

American College of Radiology, Atlantic City, Haddon Hall, June 7 Mr. Mac F. Cahal, 20 N. Wacker Drive, Chicago 6, Executive Secreta

American Dermatological Association, Murray Bay, Quebec, Can., June 1-5. Dr. Harry R. Foerster, 208 E. Wisconsin Ave., Milwaukee, Wis., Secretary.

American Diabetes Association, Atlantic City, Chalfonte-Haddon Hall, June 7-8. Dr. Cecil Striker, 1019 Provident Bank Bldg., Cincinnati 2, Secretary.

American Geriatrics Society, Atlantic City, Hotel Brighton, June 5-7. Dr. Malford W. Thewlis, 25 Mechanic St., Wakefield, R. I., Secretary.

American Heart Association, Atlantic City, Hotel President, June 6-7. Dr. Howard B. Sprague, 50 W. 50th St., New York, Secretary.

American Medical Women's Association, Atlantic City, Hotel Claridge, June 7-8. Dr. Helen F. Schrack, 216 N. Fifth St., Camden, N. J., Secretary.

American Neisserian Medical Society, Atlantic City, Marlborough-Blenheim Hotel, June 8. Dr. William L. Fleming, 750 Harrison Ave., Boston, Secretary.

American Neurological Association, Atlantic City, Marlborough-Blenheim Hotel, June 16-18. Dr. Walter O. Klingman, 195 Ft. Washington Ave., New York 32, Secretary.

American Ophthalmological Society, Hot Springs, Va., June 5-7. Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

American Physiotherapy Association, Pacific Grove, Calif., July 6-12. Miss Mildred Elson, 1790 Broadway, New York 19, Secretary.

American Proctologic Society, Atlantic City, June 7-8. Dr. Harry E. Bacon, 2031 Locust St., Philadelphia 3, Secretary.

American Radium Society, Atlantic City, June 8. Dr. Hugh F. Hare, 605 Commonwealth Ave., Boston 15, Secretary.

American Rheumatism Association, Atlantic City, Ritz-Carlton Hotel, June 7. Dr. Richard H. Freyberg, 321 E. 42d St., New York 17, Secretary.

American Society for the Study of Sterility, Atlantic City, Hotel Strand, June 7-8. Dr. John O. Haman, 490 Post St., San Francisco 2, Secretary.

American Society of Electroencephalography, Atlantic City, Marlborough-Blenheim Hotel, June 13-14. Dr. Robert S. Schwab, Massachusetts General Hospital, Boston 14, Secretary.

American Therapeutic Society, Atlantic City, Chalfonte Hotel, June 6-7. Dr. Oscar B. Hunter, 1835 I St., N. W., Washington 6, D. C., Secretary.

American Urological Association, Buffalo, N. Y., Hotel Statler, June 30-July 3. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Association for the Study of Internal Secretions, Atlantic City, June 6-7. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Idaho State Medical Association, Sun Valley, June 16-19. Dr. William B. Handford, Caldwell, Secretary.

Maine Medical Association, York Harbor, Marshall House, June 22-24. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Minnesota State Medical Association, Duluth, June 30-July 2. Dr. B. B. Souster, Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Montana, Medical Association of, Missoula, June 26-28. Dr. H. T. Caraway, 115 N. 28th St., Billings, Secretary.

National Gastroenterological Association, Atlantic City, Hotel Chelsea, June 4-6. Dr. G. Randolph Manning, Room 319, 1819 Broadway, New York, Secretary.

National Tuberculosis Association, San Francisco, June 16-19. Dr. F. D. Hopkins, 1790 Broadway, New York 19, Executive Secretary.

New Hampshire Medical Society, Portsmouth, Hotel Wentworth, June 19-20. Dr. Carleton R. Metcalf, 5 South State Street, Concord, Secretary.

South Dakota State Medical Association, Rapid City, May 31-June 3. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

Wyoming State Medical Society, Sheridan, June 23-25. Dr. George E. Baker, 226 E. 2d St., Casper, Secretary.

Medical Legislation

STATE LEGISLATION

Alabama

Bills Introduced.—H. 136 proposes to authorize counties to **levy a tax** for the purpose of acquiring, constructing operating, equipping or maintaining county or other public hospitals and public health facilities. H. 141 and S. 90 propose the enactment of a **hospital planning and construction act** to provide funds to the state board of health for the planning and construction of state owned and other public and nonprofit hospitals in the state. H 151 and S. 97, to amend the **law relating to marriages**, propose that each applicant for a marriage license shall file a certificate signed by a legally licensed physician in Alabama, or in the state where the applicant resides, certifying that the applicant is not infected with syphilis in a communicable stage The present law requires such an examination for males only S 36 proposes an additional appropriation to the **University of Alabama Medical College** in the sum of $56,750 each for two years S 102 proposes the establishment of an **advisory council** to consult with the state board of health in planning for, acquiring, constructing, equipping, maintaining and supervising hospitals, health centers and related facilities for the treatment of disease.

California

Bill Introduced.—S. 763 proposes the enactment of a law regulating **health care expense contractors.**

Bills Passed.—A. C. A 23, which passed the house May 13, proposes an **amendment to the constitution** to the effect that no provision in the constitution shall be construed as a limitation on the power of the legislature by general law to give or lend state money or other assistance for the construction of hospitals, health centers and related facilities to counties, cities and counties, cities, local hospital districts, other public districts authorized to construct hospitals, etc. A 2428, which passed the house May 14, to amend the business and professions code, proposes under certain circumstances to authorize licentiates of other states to act as **resident or assistant resident physicians** and surgeons in state hospitals for a period of not exceeding one year

Bill Enacted.—S 250, which has become chapter 234 of the Laws of 1947, repeals the existing law relating to the examination and licensure of **trained hospital attendants.**

Connecticut

Bill Passed.—S 170, which passed the house May 19, proposes to broaden the scope of activities of the **bacteriologic laboratory** so as to conform with those of a modern public health laboratory.

Florida

Bills Introduced.—H. 257 has previously been reported as proposing a law for the licensing, inspecting and regulating of hospitals and the creation of an **advisory hospital council.** Two amendments were added to this bill by the house committee on May 13 The first would exempt from its provisions the establishment or operation of any hospital for the practice of the religious tenets of any church in the ministration to the sick and suffering by mental or spiritual means without the use of any drug or remedy, provided the statutes or regulations on sanitation are complied with. The second would prohibit the rule making authority from making any rule which would have the effect of denying a license to a hospital or other institution solely by reason of the school or system of practice employed or permitted to be employed by physicians therein, provided that such school or system of practice is recognized by the laws of the state. H. 815 proposes to authorize the **appointment of medical examiners** and assistant medical examiners in each county to perform functions similar to those of a coroner. S. 614 proposes to require the state board of health to develop and maintain a **state blood program** for the purpose of coordinating and integrating the services of autonomous, nonprofit blood banks, to organize additional blood banks and to establish subsidiary blood banks and distribution centers in order that these therapeutic products shall be made available at hospitals and to all physicians licensed to practice in Florida and to insure that the supply of blood and blood products shall be adequate to meet reasonable requirements.

Bills Passed.—H. 253, which passed the senate May 14, proposes to authorize persons to donate and give their eyes for **eyesight restoration** purposes by last will and testament and authorizes any state, county, district or other public hospital to purchase and provide the necessary facilities and equipment to establish and maintain an eye bank for restoration of sight purposes H. 440, which passed the house May 15, proposes to make it unlawful for tax collectors in the several counties to issue **state and county occupational licenses** to any person applying for license to practice medicine in any of its branches unless and until proof of current qualification and competency, as established by certificate or license issued by the state boards duly constituted and legally authorized to determine qualification and competency, be exhibited at the time of making such application S. 151, which passed the house May 9, to amend the law relating to the **practice of massage,** proposes to redefine the meaning of the practice so as to include the use of electrical apparatus.

Maine

Bills Enacted.—S 164, which has become chapter 191 of the Laws of 1947, creates a commission to investigate and study the feasibility and desirability of establishing a **medical school in the state of Maine.** S 419, which has become chapter 391 of the Laws of 1947, authorizes the governor to appoint an **advisory hospital council** to advise and consult with the department of health and welfare in carrying out the administration of the existing hospital survey act.

Michigan

Bill Passed.—H. 451, which passed the house May 16, proposes the enactment of a law requiring the licensing, regulation and **inspection of hospitals** and related institutions and the appointment of an advisory institutional council.

Missouri

Bill Passed.—S. 157, which passed the senate May 14, to amend the sales tax act, proposes that purchases of **tangible personal property** made by duly licensed physicians, dentists and veterinarians and used in the practice of their professions shall be deemed to be purchases for use or consumption and not for resale

New Hampshire

Bill Introduced.—H. 456 proposes the creation of a **mental hygiene commission** to manage and conduct mental hygiene clinics primarily for the psychiatric and psychologic study and treatment of such children as may be committed to its care.

Oklahoma

Bills Enacted.—S 76, which was approved May 16, requires every prospective **teacher in the public schools** to have a medical examination for the purpose of determining physical qualifications in accordance with regulations prescribed by the state board of health. S. 100, which was approved May 16, creates within the state health department a division to be known as the **Division of Preventive Dentistry** to administer a program of dental care, consultation, research and health education designed to improve the dental health of the people of the state.

Pennsylvania

Bills Passed.—H. 1043, which passed the house May 13, proposes, among other things, to prohibit the **sale of benzedrine,** and other, inhalers at retail. S. 335, which passed the house May 14, to amend the law relating to **consumer credit,** proposes that the act shall not apply to nonprofit corporations organized under the laws of the state having memberships consisting exclusively of duly licensed physicians, surgeons and dentists operated exclusively for and by their members and engaged in, among other activities, the financing of personal obligations arising from the rendering of professional services by the members of such nonprofit corporations which are limited strictly to medical surgical, dental, operative, diagnostic and treatment services or nursing and hospital care

South Carolina

Bills Enacted.—S. 254, which has become chapter 399 of the Laws of 1947, provides that **osteopathic physicians** duly licensed to practice their profession under the laws of the state are authorized and shall certify birth and death certificates in the same manner as is now prescribed by law for other physicians S. 721, which has become chapter 511 of the Laws of 1947, creates a combination state **hospital construction act** and hospital licensing law.

Texas

Bill Introduced.—H. 833 proposes to authorize the **state board of health** to receive gifts, donations and contributions from various sources for the purpose of building, constructing, maintaining and operating a medical research laboratory.

Bills Passed.—H. 138, which passed the house May 5, proposes the creation of a state board of **examiners in the basic sciences.** A house floor amendment of May 1 proposes to exempt from the basic science law any chiropractor who is a graduate of a reputable chiropractic college in the United States and who has practiced chiropractic for three years immediately preceding the effective date of this act and who has resided in Texas for two years immediately preceding the effective date of this act and who has never had a license to practice any branch of the healing art canceled by any American or Canadian state, province or territory. H. 503, which passed the house May 6, proposes the enactment of a state hospital survey and construction act requiring a **statewide survey of hospital facilities** and the preparation of a program for the construction of additional needed facilities The proposal also requires the appointment of an advisory hospital council and the establishment of regulations for the purpose of obtaining federal funds to assist in survey and construction programs The administration of this proposal would be under a division of hospital survey and construction in the department of health S. 120, which passed the senate April 28, to amend the penal code, proposes to make it unlawful for any physician or other practitioner of the art of healing **to advertise special skills,** definite prices or the use of superior qualities of medicine, material, devices, etc. in the performance of professional service.

Wisconsin

Bills Passed.—S. 104, which passed the senate May 14, proposes regulations for the licensing, inspecting and **regulating of hospitals** within the state. S. 105, which passed the house May 19, proposes the enactment of a **state hospital survey and construction act** requiring a survey of hospitals and health facilities in the state and the preparation of a program for the construction of additional needed facilities The proposal would require the appointment of an advisory hospital council and would authorize the state board of health to apply for and receive federal funds to assist in such survey or construction program. S. 156, which passed the house May 19, to amend the law relating to the **licensing of osteopaths,** proposes to require applicants for a license to practice osteopathy to have completed at least twelve months' internship in a reputable osteopathic hospital or its equivalent.

GOVERNMENT SERVICES

PUBLIC HEALTH SERVICE

NEW DIVISION OF TROPICAL DISEASES

The Surgeon General, Dr. Thomas Parran, announces that the Public Health Service has established a new division of tropical diseases in the National Institute of Health, Bethesda, Md. Heading the new unit will be Willard H. Wright, formerly chief of the zoology laboratory and, during the war, field director of the Commission on Schistosomiasis in the Southwest Pacific and Japan. Dr. Wright received his D.V.M. degree from George Washington University in 1917 and a Ph.D. in 1935. He is a member of the American Academy of Tropical Medicine, the American Society of Parasitologists, the Helminthological Society of Washington and the New York Academy of Sciences.

NEW CHIEF OF THE OFFICE OF DERMATOLOGY

Paul C. Campbell Jr., Surgeon, has been appointed chief of the Office of Dermatology, Industrial Hygiene Division, U. S. Public Health Service, succeeding Dr. Louis Schwartz, who will retire July 4 after forty-one years of service. Dr. Campbell, who has been on duty in the office of dermatology since 1944, has been investigating dermatitis hazards in various industries. Before entering the Public Health Service in 1941 he was for several years a resident in dermatology and syphilology at the Edward J. Meyer Memorial Hospital in Buffalo.

PERSONAL

Medical Director (R) Russell S. Ferguson, Washington, D. C., has been ordered to active duty and to report to the U. S. Marine Hospital, San Francisco.

CALLED TO ACTIVE DUTY

The U. S. Public Health Service reports that the following officers have been called to active duty in either the reserve corps or the regular corps and have been directed to report to the stations opposite their names:

Azulay, Abraham, assistant surgeon (R), U. S. P. H. S., Medical Center, Hot Springs National Park, Ark.

Cohart, Edward M., surgeon (R), U. S. P. H. S., District 1, 15 Pine St., New York.

Davenport, Dennis D., assistant surgeon (R), District Coast Guard Office, Seattle.

Green, James R., assistant surgeon (R), U. S. Marine Hospital, Memphis, Tenn.

Mahe, George A., Jr., assistant surgeon (R), U. S. Penitentiary, Atlanta, Ga.

Peck, James F., assistant surgeon (R), U. S. P. H. S., Medical Relief Station, Louisville, Ky.

Velat, Clarence A., assistant surgeon (R), U. S. P. H. S., States Relations Division, Washington, D. C., Bethesda Station.

OFFICERS RELEASED FROM SERVICE

U. S. Public Health Service headquarters reports that the following medical officers have been terminated, inactivated or retired and directed to proceed to the city opposite their name:

Abrams, Henry, surgeon (R), Princeton, N. J.
Ausubel, David P., assistant surgeon (R), Bronx, N. Y.
Kintner, Burton E., S. A. surgeon (R), Elkart, Ind.
Rodman, Peter P., S. A. surgeon (R), Aberdeen, Md.
Rothfeld, Edmond, S. A. surgeon (R), Cincinnati.
Warhaftig, Melvin V., assistant surgeon (R), Hillside, N. J.

MISCELLANEOUS

DISTRIBUTION OF "HEAVY WATER"

The United States Atomic Energy Commission has announced plans for the distribution of heavy water and deuterium gas to qualified research institutions in the United States.

Heavy water was produced in connection with the atomic energy operations and now is available in sufficient quantities for domestic research purposes outside the government's atomic energy program. The Stuart Oxygen Company of San Francisco, which will make the distribution under contract with the commission, will convert heavy water to deuterium gas for applicants who need deuterium in the latter form.

Applicants for deuterium oxide (heavy water) and deuterium gas will be charged an amount sufficient to cover handling and distribution charges of the contract distributor. The price schedule for heavy water is 50 cents per gram for the first hundred grams and 30 cents per gram thereafter and for deuterium gas $1 per liter (at normal temperature and pressure) for the first hundred liters and 80 cents per liter thereafter. Prices are based on orders calling for single deliveries to the applicant.

Applications will be handled in the same manner as requests for radioactive isotopes produced in the pile at Oak Ridge and distributed by the Monsanto Chemical Company. Application forms can be obtained from the Atomic Energy Commission, Research Division, Isotopes Branch, Oak Ridge, Tenn. Applications will be screened by the subcommittees of the Advisory Committee on Isotope Distribution in order to insure the most efficient use of the materials. Approved applications will be returned to the applicant for transmittal to the contract distributor. Users, as in the case of radioisotopes, will be required to furnish the commission reports on the results of experiments carried on with heavy water and deuterium. Applicants must agree not to transfer the materials to another user without the consent of the commission.

Heavy water contains the heavy stable isotope of hydrogen referred to as deuterium and is symbolized by D_2O. It is found in ordinary water at a ratio of 1 to every 4,500 parts of ordinary water. The heavy hydrogen isotope has twice the atomic mass of the ordinary hydrogen atom.

Heavy water and deuterium have numerous uses in physics, chemistry and biology. In nuclear physics deuterium is of special value and has a number of uses:

1. High voltage accelerators such as the cyclotron use deuterium as a source of bombarding particles in studying nuclear reactions. Deuterium bombardment of light elements results in a large yield of high energy neutrons.
2. Heavy water is an effective moderator, serving to slow down the fast neutrons. Ordinary water will also slow down fast neutrons but absorbs a large proportion of the neutrons. The relatively small neutron absorption of heavy water makes it useful as a moderator in certain types of chain reacting piles. Amounts made available under this plan of distribution will permit research on the proportion of heavy water as a moderator.
3. Heavy water is used in determining the energy of gamma rays through photo production of neutrons. This is useful in studying the energy of gamma rays.

Deuterium is extensively used as a tracer for hydrogen in biologic and chemical processes. Hydrogen has been used to study the metabolism of normal and malignant cells in attempts to discover the nature and causes of cancer. Heavy water can also be used as a tracer in studying the exchange of water in various systems; for example, between a fish and its environment. It can also be used to study the fluid balance in man.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

CALIFORNIA

Fund to Fight Heart Disease.—A committee representing the Los Angeles County Tuberculosis and Health Association will jointly administer the A. M. Roberts Memorial Fund to fight heart disease. The fund was established through the efforts of the late Dr. Archie M. Roberts, formerly of the University of Southern California School of Medicine, Los Angeles, and until his death, April 1, president of the Los Angeles Heart Association. Contributions will be used for the care of children with rheumatic fever and other heart ailments and for research.

Changes in Health Officers.—Recent additions to the staff of the state department of public health include Dr. James W. Ellis, Washington, D. C., who will be cancer consultant with the bureau of chronic diseases. Dr. Ellis comes to the department following thirty years of service with the navy. He is a graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1915, was certified by the American Board of Surgeons and was medical director in the U. S. Navy with the rank of captain. Dr. Harvey F. Hendrickson, San Francisco, has been appointed to the bureau of hospital inspection as an assistant to Dr. Julius B. Askew. Dr. Hendrickson, a graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1927, was a major in the medical corps of the army. During the past year he has been assistant superintendent of the San Francisco Hospital.

COLORADO

Rocky Mountain Cancer Conference.—This conference will be held in Denver July 9 and 10 at the Shirley-Savoy Hotel with the following program:

Dr. Ashley W. Oughterson, New York, Aims of the American Cancer Society.
Dr. Hugh J. Morgan, Nashville, Tenn., Importance of History and Physical Examination in the Recognition of Cancer.
Dr. Harry C. Solomon, Boston, Psychiatric Implications of Cancer.
Dr. Shields Warren, Newton, The Radiosensitivity of Tumors.
Dr. Edwin C. Ernst, St. Louis, Use of the Roentgen Ray in the Treatment and Diagnosis of Cancer.
Dr. Frank Adair, New York, Diagnosis and Treatment of Breast Tumors.
Dr. Charles B. Huggins, Chicago, Carcinoma of the Prostate.
Dr. Eugene F. Traub, Jackson Heights, N. Y., The So-Called Premalignant Eruptions of the Skin.
Dr. Joe Vincent Meigs, Brookline, Mass., Carcinoma of the Lip and Mouth.

CONNECTICUT

Rural Health Conference.—The Connecticut State Medical Society and the University of Connecticut will sponsor a rural health conference at the university on July 16. Members of the society's rural health committee now preparing plans for the conference include Drs. Norman H. Gardner, East Hampton, chairman; Gert S. Gundernatsch, Sharon; David H. Bates, Putnam, and William H. Upson, Suffield.

Dr. Walker Appointed to Public Health Council.—The governor recently appointed Dr. W. Bradford Walker, Cornwall, to the Connecticut Public Health Council, effective July 1, for a term of six years. Formerly president of the Connecticut Public Health Association and past president of the Litchfield County Medical Association, Dr. Walker will succeed Dr. David R. Lyman, who is retiring from the council following eighteen years of continuous membership. Dr. Lyman is a past president of the Connecticut State Medical Society, the New Haven County Medical Association, the American Sanatorium Association and the National Tuberculosis Association.

ILLINOIS

The Fifty-Year Club.—Fifty years of service by each of five Illinois physicians have been recognized by Illinois county medical societies. Champaign County Medical Society presented certificates of membership in the "Fifty-Year Club" and gold buttons signifying fifty years of medical service to Drs. William E. Schowengerdt, Champaign; Charles H. Spears, Champaign; Emerson M. Brewer, Rantoul, and Joseph Brayshaw, Homer. At Mount Vernon Dr. Moss Maxey, at a dinner given by the Jefferson County Medical Society May 8, was likewise honored. Membership in the club is awarded by the Illinois State Medical Society through county organizations.

New General Hospitals.—Formal opening and public inspection of the new $150,000 Milan General Hospital, Milan, took place April 13 with religious, political and civic leaders in attendance. The hospital has been under construction for more than a year. Dr. Edwin F. Condon is president and director. ——A $1,400,000 building program will begin in August for the expansion of MacNeal Memorial Hospital, Berwyn. The present capacity will be doubled, and quarters for nurses will be provided. The new addition will be four stories in height, except a center portion which will be five stories. A new suite of operating rooms, an enlarged x-ray department, delivery and labor rooms and other laboratories will be added.

Chicago

Hilton Hotels Appointment.—Richard L. Collison, director of sales of the Palmer House, has been appointed director of sales for the entire Hilton Hotel chain. He will continue, however, to make his headquarters in Chicago.

Million Poliomyelitis Leaflets to be Sent to Parents.—The Cook County chapter of the National Foundation for Infantile Paralysis will distribute a million leaflets explaining precautions to be taken during the summer. The leaflets will be delivered to public and parochial schools throughout Chicago and Cook County for children to take home to their parents. Bulk distribution will also be made to large employers. A card included with the pamphlet urges that, if poliomyelitis occurs, a physician be called at once and that the Cook County chapter, National Foundation for Infantile Paralysis, be called if help is needed.

Symposium in Honor of Illinois President.—An inaugural symposium in honor of President George D. Stoddard, University of Illinois, was held May 15 in the lecture hall of the University of Illinois College of Medicine. Speakers were Dr. Roscoe R. Spencer, director of the National Cancer Research Institute, Bethesda, Md.; Dr. Edmund V. Cowdry, professor of anatomy and head of the department, Washington University School of Medicine, St. Louis, "Geriatrics," and Dr. Austin M. Brues, associate professor of medicine, University of Chicago Institute of Radiology and Biophysics, "Medical Implications of Atomic Research." Dr. Anton J. Carlson, professor emeritus of the University of Chicago, was a guest speaker at a luncheon.

KENTUCKY

Three Clinical Professors to Retire.—At the end of the school year three Louisville physicians will retire as clinical professors from the University of Louisville School of Medicine, Louisville: Dr. Irvin Abell, clinical professor of surgery, president of the American College of Surgeons and formerly President of the American Medical Association; Dr. Bernard Asman, clinical professor and head of the department of proctology, and Dr. Charles W. Hibbitt, clinical professor of obstetrics and gynecology. All three graduated in the class of 1897, and all have offices in the same building, where they will continue their private practice. As professors emeritus they will be consultants to the medical school faculty.

LOUISIANA

Ochsner Foundation Hospital.—Dedication exercises were held April 13 for the foundation hospital, recently purchased by the Alton Ochsner Medical Foundation, New Orleans. The former army hospital wards have been converted into individual cubicles for private patients. Seven patient buildings with 161 beds are now in operation. Eventual plans are for a capacity of 300 beds.

Poliomyelitis Preparedness Conference.—The Louisiana State Department of Health, the National Foundation for Infantile Paralysis and the Orleans chapter of the National Foundation jointly will hold a poliomyelitis preparedness conference at the St. Charles Hotel, May 30-31. Among the speakers at the two day session will be Dr. Waldo L. Treuting, New Orleans, Louisiana State Board of Health, "Public Health Regulations and Facilities for Treatment of Infantile Paralysis Cases"; Dr. Oliver P. Daly, director, Charity Hospital of Louisiana, "The Charity Hospital System in Louisiana"; Dr. Kenneth S. Landauer, Geneva, N. Y., director of medical care, National Foundation, "Diagnosis and Treatment of Acute Poliomyelitis." Saturday a symposium on infantile paralysis will be held, subjects being pediatric aspects, modes of spread, orthopedic considerations, nursing advisory service and end results. The American Red Cross will present nursing problems involved in an infantile paralysis epidemic.

MASSACHUSETTS

Retired Navy Officers Appointed Health Officers.—Dr. Robert E. S. Kelley, captain, U. S. Navy (retired), has been appointed to the Massachusetts Department of Public Health as physician in charge of the second mobile unit of the State Blood Donor Program. Dr. Walter J. Pennell, captain, U. S. Navy (retired), has been appointed health officer of the Northeastern District of the Massachusetts Department of Public Health. Dr. Paul Richmond, captain (MC), U. S. Navy (retired), Washington, D. C., has been appointed health officer of the Worcester district of the Massachusetts Department of Public Health.

Dr. Faulkner Appointed Dean at Boston University.—Dr. James M. Faulkner, Boston, will assume his duties as dean of the Boston University School of Medicine, June 1, replacing Dean Donald G. Anderson, Boston, newly appointed secretary of the Council on Medical Education and Hospitals of the American Medical Association. Dr. Faulkner received his medical degree at Harvard Medical School, Boston, in 1924. He was assistant resident physician at the Rockefeller Institute Hospital, New York, in 1926, and the Johns Hopkins Hospital 1926-1927. He was a consultant in medicine at the U. S. Marine Hospital in Boston and director of the first and third medical services at Boston City Hospital, as well as a professor of medicine at Tufts College Medical School, Boston.

NEVADA

State Board Resumes Reciprocity.—At the May 5 meeting of the Nevada State Board of Medical Examiners the board unanimously voted to rescind the rule of suspension of reciprocity and to resume reciprocity. It also voted to meet only twice a year, i. e., in May and November, at which time it will hold both written examinations and oral reciprocity examinations.

NEW JERSEY

Society Organized.—The New Jersey Obstetrical and Gynecological Society was organized by about 125 members of the Medical Society of New Jersey at its annual meeting in Atlantic City April 23. The organization elected the following officers: Drs. Samuel A. Cosgrove, Jersey City, president; Herschel S. Murphy, Roselle, president-elect; George B. German, Camden, vice president; Benjamin Daversa, Spring Lake, secretary, and Osborne F. Christensen, Hackensack, treasurer. The society expects to hold its second meeting in Jersey City in October.

Dr. Donohoe Honored.—The medical staff of Bayonne Hospital and Dispensary will present Dr. Lucius F. Donohoe, medical director, with a portrait in oil in recognition of his services to the hospital, at a testimonial dinner June 5. This year marks his twentieth anniversary as medical director and his thirtieth anniversary as president of the medical staff. Dr. Donohoe served with the A. E. F. in France in World War I as a lieutenant colonel in the Medical Corps. He was commended in a citation for meritorious service by the American Expeditionary Forces. The republic of France conferred on him the Citation and Certificate of the Order of University Palms, grade of Officer of Academy, and later made him a Chevalier of the Legion of Honor.

NEW YORK

Sesquicentennial of Westchester County Society.—The Medical Society of the County of Westchester marked the one hundred and fiftieth consecutive year of its existence May 8. The society's sesquicentennial year will be commemorated by the publication of a volume of the history of the society to date. Dr. Laurence D. Redway, Ossining, will prepare the volume, which will be distributed at the annual meeting in November.

Professor Wiggers Comes to Albany Medical College.—Harold C. Wiggers, Ph.D., Chicago, will take over duties as head of the department of physiology and pharmacology at Albany Medical College July 1. The 38 year old teacher and research worker has been associate professor of physiology at the University of Illinois College of Medicine, Chicago, since 1943. He has done research on the coronary circulation, cardiodynamics, ovulation potentials and bioelectric phenomena. Dr. Wiggers received his bachelor's degree from Wesleyan University in 1932 and his doctor of philosophy from Western Reserve University in 1936. At Harvard Medical School, Boston, he held the W. T. Porter Fellowship. He was an instructor at Columbia University College of Physicians and Surgeons, New York, from 1937 to 1942 and was assistant professor at Western Reserve School of Medicine in 1942-1943.

Dr. Godfrey Retires.—Dr. Edward S. Godfrey Jr., state commissioner of health, retired May 1 after nearly thirty years in the state department of health. After graduation from the University of Virginia Department of Medicine, Charlottesville, he served both Arizona and Illinois before becoming epidemiologist in the New York State Department of Health. In 1920 he was appointed director of the division of communicable diseases and in 1931 director of local health administration. From 1928 to 1935 he served part time as clinical professor of epidemiology at the Columbia University College of Physicians and Surgeons. In 1936 he was appointed state commissioner of health. Dr. Godfrey has contributed many articles to the literature on public health, notably the report of a study of measles in children's institutions in the state outside of New York City. He is a member of numerous public health and medical societies.

New York City

Proposed Study of Rheumatic Heart Disease.—New York University College of Medicine in cooperation with the City Health Department will make a study of rheumatic fever and rheumatic heart disease among school children in the Lower East Side district next fall. The objective will be to develop efficient detection, follow-up and supervision which may be adopted on a citywide basis by the department of health. The study will be directed by Dr. Elvira M. DeLiee. Financial support comes from the New York Heart Association, U. S. Public Health Service, New York Department of Education, Rheumatic Fever Council of the American Heart Association, U. S. Children's Bureau, New York School of Social Work, Metropolitan Life Insurance Company and other departments of the university.

Master Plan for City Hospitals.—The hospital council of greater New York announced its master plan for city hospitals and related facilities last month. Based on the city's estimated 8,000,000 population requirements of 1950, the plan calls for 129,000 hospital beds, 33,600 for general care, 8,000 for convalescent care, 16,000 for long term illnesses, 800 for acute communicable diseases, 6,600 for tuberculosis and 64,000 for psychiatric care. It calls for eight regional hospitals and sixty-four community hospitals. The plan was drawn with the idea that distribution and location of hospital facilities should be determined by the needs of the people, the need for teaching and training programs and the need for medical research. The study has been endorsed by Mr. Edwin A. Salmon, chairman of the City Planning Commission, and Drs. John B. Pastore, executive director of the Hospital Council; George Baehr, president of the New York Academy of Medicine; William B. Rawls, representing the medical societies of the city; Claude W. Munger, director of St. Luke's Hospital; Edward M. Bernecker, city commissioner of hospitals, and Mr. Arthur A. Ballantine, chairman of the United Hospital Fund and the Greater New York Fund.

PENNSYLVANIA

Second Councilor District Meeting.—A meeting of the second councilor district of the Medical Society of the State of Pennsylvania will be held June 4 in the Masonic Temple, Allentown, at 12 noon. On the scientific program Dr. Chauncey L. Palmer, Pittsburgh, will speak on "Legislative Trends in the 1947 Session of the Pennsylvania Legislature"; Dr. Howard K. Petry, Harrisburg, president of the state society, "Indications for and Technic of Electro Shock," and David R. Perry Harrisburg, secretary to the governor, "Medicine Today and Tomorrow." Dr. Petry will present fifty year testimonials to the honor guests: Drs. Andrew Godfrey, Montgomery County; Chester K. Kistler, Berks County; William C. LeCompte, Bucks County; John B. Roxby, Delaware County, and Charles H. Schlesman, Lehigh County.

Seventh District Meeting.—The Seventh Councilor District Meeting of the Medical Society of the State of Pennsylvania was held May 9 at Williamsport with about 135 doctors and members of Woman's Auxiliaries in attendance. Dr. Elmer Hess, Erie, president-elect, presented the society's fifty year testimonial to the honor guest, Dr. John L. Mansuy, Ralston. Among the speakers were Dr. Joseph S. Lawrence, Director, Washington Office, Council on Medical Service, A. M. A., Washington, D. C., who spoke on "Preventive Medicine: Facts and Fancies"; Dr. Howard K. Petry, Harrisburg, president, Medical Society of the State of Pennsylvania, "Role of the State and the Local Community in a Mental Health Program," and Dr. Pascal F. Lucchesi, superintendent, Philadelphia General Hospital, "The Family Doctor's Role in Public Health Preventive Medicine."

Philadelphia

Shmookler Memorial Lecture.—The H. B. Shmookler Memorial Lecture of Mount Sinai Hospital will be delivered by *Dr. Louis N. Katz*, Chicago, on "The Control of the Coronary Circulation," June 5, at 9 p. m. in the nurses' conference room.

Dr. Long to Head Tuberculosis and Health Association.—Dr. Esmond R. Long, director of the Henry Phipps Institute, University of Pennsylvania, has been elected president of the Philadelphia Tuberculosis and Health Association to succeed Dr. Charles J. Hatfield, president of the organization for twenty-four years. The board has made Dr. Hatfield president emeritus in recognition of his long period of service.

RHODE ISLAND

Society News.—The Rhode Island Society of Industrial Physicians and Surgeons, Inc., have elected the following officers for the coming year: Drs. Richard F. McCoart, Providence, president; Thomas A. Egan, Providence, vice president; James P. Deery, Providence, secretary, and Robert T. Henry, Pawtucket, treasurer.

TEXAS

State Medical Election.—At the annual meeting, May 8, of the State Medical Association of Texas the following officers were elected: president, Dr. Tate Miller, Dallas; vice presidents, Drs. Frank A. Selecman, Dallas; Ximie R. Hyde, Fort Worth, and Elmer W. Jones, Wellington; secretary, Dr. Holman Taylor, Fort Worth, and treasurer, Dr. Thomas H. Thomason, Fort Worth. The next annual session will be in Houston.

WEST VIRGINIA

State Medical Election.—The West Virginia State Medical Association elected the following officers at the annual meeting in Charleston May 13: president, Dr. Thomas F. Bess, Keyser; first vice president, Dr. Spencer L. Bivens, Charleston; second vice president, Dr. Harold Van Hoose, Man, and treasurer, Dr. Thomas M. Barber, Charleston. Dr. Ivan Fawcett, Wheeling, was chosen A. M. A. delegate with Dr. James L. Wade, Parkersburg, alternate. Both succeed themselves. Total doctor registration broke all state records, 559 compared with a previous high of 512 at Clarksburg in 1937. The next annual meeting will be held at the Greenbrier Hotel, White Sulphur Springs, July 12-14, 1948.

PUERTO RICO

Health Legislation in Puerto Rico.—The governor of Puerto Rico, Hon. Jesus T. Pinero, has recently approved the following appropriation bills passed by the insular legislature in its regular annual session meeting February to April, to carry out the government's health and sanitation program during the coming fiscal year:

House bill 1374, authorizing a hospital survey of the island to determine the need for additional hospital facilities.

Act 69, appropriating the sum of $150,000 to the department of health to carry on its malaria control program during the fiscal year.

Act 33, appropriating the sum of $51,000 for improvements to the tuberculosis hospital in the city of Ponce.

Act 41, appropriating the sum of $55,000 for improvements to the tuberculosis hospital in the city of Mayaguez.

Act 43, appropriating the sum of $25,000 to continue the enlargement and new constructions to municipal hospitals in the island.

Act 44, appropriating $100,000 for the acquisition, transportation and installation of latrines in the rural areas.

Act 48, appropriating $38,000 for improvement to the tuberculosis hospital in the city of Guayama.

Act 53, appropriating $187,500 to the University of Puerto Rico for scholarships for poor medical students to be sent to colleges and universities in the United States.

Act 392, providing for the construction of a municipal hospital in Piedras.

Act. 413, appropriating $75,000 for improvements and enlargement to the municipal hospitals in the city of San Juan and for purchase of equipment for these hospitals.

Act 112, appropriating $120,000 for repairs, extension and equipment of the Hospital for the Lepers, established in the city of Trujillo Alto.

Act 410, appropriating $6,250,000 to carry on a vigorous slum clearance program in Puerto Rico.

Act 437, authorizing the administrator of the State Insurance Fund to use the services of American and foreign physicians, who shall be contacted by the insular Department of Health.

Act 444, to prohibit contamination of potable water sources in Puerto Rico, to provide penalties for violation of this act and to create a commission to intervene in such cases.

Act. 37[illegible] nent of health to copy in microfilm all the birth [illegible] nses and death certificates that appear in the ol[illegible] Rico in order to preserve such documents, an[illegible] crofilms be made of all such documents issued by [illegible] bureau of the department of health to interested parties.

Act 380, providing that credit as alternates be granted to all physicians who served in hospitals during active military service in the armed forces of the United States, who will serve in government institutions in Puerto Rico.

GENERAL

Pan American Congress of Pediatrics.—The first Pan American Congress of Pediatrics will be held at the Mayflower Hotel, Washington, D. C., July 9 to 12, under the auspices of the American Academy of Pediatrics. Dr. Felix Hurtado Galtes, Havana, will be the presiding officer.

Percy Jones Hospital Reunion.—The Percy Jones Hospital reunion will be held at Longport Inn, 35th and Atlantic avenues, Longport, N. J., Monday, June 9. 7 p. m. Further information can be obtained from Mrs. Kathryn S. Read, 5407 Atlantic Avenue, Ventnor, N. J., phone Atlantic City 2-3509.

Clinical [illegible] Atlantic City Meeting.—The Atlantic [illegible] merican Society of Clinical Pathologists [illegible] ings as June 4-8 has been canceled in [illegible] the United Nations. The society will [illegible] 27-30 instead.

Appoint Director of Commonwealth Fund.—Dr. Donal Sheehan, professor of anatomy and lately acting dean of the New York University College of Medicine, New York, has been appointed general director of the Commonwealth Fund to succeed Barry C. Smith, who will retire September 1. Dr. Sheehan came to this country from England in 1937 to join the faculty of New York University. He recently completed a mission to Czechoslovakia for the Rockefeller Foundation.

Heart Association Appointment.—Dr. Charles A. R. Connor has been appointed associate medical director of the American Heart Association and will work with Dr. David D. Rutstein, medical director, in developing the association's program of research service and public education in diseases of the heart and circulation. Dr. Connor, who received his medical degree in 1931 and his Doctor of Science in Medicine from New York University College of Medicine, New York, in 1940, has been since 1935 instructor in medicine there. In 1946 he was named attending physician in cardiovascular disease, Lenox Hill Hospital, New York.

Dr. Waksman to Receive Passano Foundation Award.—At a presentation dinner scheduled for June 12 during the week of the Centennial Celebration in Atlantic City, Selman A. Waksman, Sc.D., New Brunswick, N. J., will receive the $5,000 Passano Foundation award for original research in the field of antibiotics culminating with his discovery of streptomycin. Dr. Waksman will give an address, "Antibiotics and Tuberculosis—A [illegible] roach," and Sir Howard Florey, Ph.D., [illegible] o was knighted for his development of [illegible] of penicillin, will give a brief address. The Passano Foundation, established in 1943 by the Williams & Wilkins Company, medical publishers, Baltimore, provides the award to encourage medical research.

Assistant Director of American College of Surgeons.—Dr. Charles F. Branch, formerly dean of Boston University School of Medicine and recently director of the Children's Hospital, Boston, has joined the staff of the American College of Surgeons in Chicago as assistant director. He will be particularly concerned with the work of the cancer committee of the college, which includes a survey and approval of cancer clinics inaugurated in 1930 and the establishment of a similar program in relation to cancer detection centers. Dr. Branch, a graduate of the University of Vermont College of Medicine, Burlington, was professor of pathology at Boston University School of Medicine and pathologist to the Massachusetts Memorial Hospitals as well as serving a number of suburban hospitals in Boston from 1926 to 1946. He is a past president of the New England Pathological Society.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery.—This society will meet at the Hotel Mayflower, Atlantic City, June 11, at 8 p. m. The speakers will include Dr. Norman N. Smith, New Haven, Conn., "Preparation of the Patient for Rhinoplasty"; Dr. Frank Turchik, Bridgeport, Conn., "Annoying Postoperative Problems in Nasal and Septal Plastic Surgery"; Dr. Samuel F. Kelley, New York, "Tantalum Implants for Correction of Postoperative Deformity Resulting from Radical Frontal Sinus Surgery"; Drs. Joseph G. Gilbert and Joseph S. Silverberg, Brooklyn, "Evaluation of the Various Types of Implants for Correction of Saddle Nose"; Dr. John F. Pick, associate in surgery, University of Illinois, Chicago, "Plastic Otorhinologic Surgery." General discussion will be opened by Dr. Francis W. White, New York.

Dr. Cori Receives Award.—Dr. Carl F. Cori, Washington University Medical School, St. Louis, was awarded the second intermediate research prize of $5,000 April 28 for distinguished achievements in the field of human metabolism extending over a period of twenty years. The award, made annually by the National Science Fund of the National Academy of Sciences in recognition of the development of original knowledge about sugar, was presented by Dr. William C. Stadie, associate professor of research medicine at the University of Pennsylvania School of Medicine, Philadelphia. The most significant contribution Dr. Cori has made is indicating how insulin influences the burning of sugar, opening the way for improved technics for the control of diabetes. His research has led to the discovery of the enzymes phosphorylase and hexokinase. More recently Dr. Cori and his wife indicated the mechanism for the release of stored blood sugar in the liver.

Norton Medical Award for Book Manuscripts.—W. W. Norton & Company are again offering the Norton Medical Award for book manuscripts written for the lay public by professional workers in the field of medicine. The publishers now set no final closing date for the submission of manuscripts which may be submitted at any time, the award not being limited to any one year. The Norton Award offers $5,000 as a guaranteed advance against royalties. Either complete manuscripts or detailed table of contents together with 100 pages of manuscript may be submitted. A folder giving details of the terms of the award may be secured from the publishers at 101 Fifth Avenue, New York 3. Books that have previously won Norton Medical Awards are "The Doctor's Job," by Dr. Carl A. L. Binger, New York; "Doctors East, Doctors West," by Dr. Edward H. Hume, New York, and "A Surgeon's Domain," by Dr. Bertram M. Bernheim, Baltimore, published this spring.

Research in Tuberculosis.—At a recent meeting the committee on medical research of the National Tuberculosis Association, New York, approved the following grants for research and allocated a total of $91,550 for these purposes for the fiscal year ending March 31, 1948:

1. Analysis of internal chemistry of the tubercle bacillus, and cataloguing of the chemical derivatives.—Dr. Ralph J. Anderson, Yale University, New Haven, Conn.
2. Investigation of pulmonary calcifications.—Dr. Amos Christie, Vanderbilt University, Nashville, Tenn.
3. Synthesis of biologic reaction of different chemical fractions of tubercle bacillus provided by chemical laboratories.—Dr. Charles A. Doan, Ohio State University, Columbus, Ohio. (This study is supported by funds contributed by the Ohio Tuberculosis and Health Association.)
4. Determination of the course of tuberculosis in children exposed to the disease from infancy to adult life.—Dr. Edith M. Lincoln, Bellevue Hospital, New York.
5. Determination of the relation of tubercle bacillus carbohydrates to tuberculosis and to its immunity.—Dr. Sidney Raffel, Stanford University, Calif. (This is a cooperative study partially supported by funds contributed by the California Tuberculosis and Health Association.)
6. The chemistry of tuberculin.—Dr. Florence B. Seibert, Henry Phipps Institute, Philadelphia.
7. Provision of base line data on the serum content of different globulins and polysaccharides in normal animals used for research in tuberculosis.—Dr. J. W. Willliams, University of Wisconsin, Madison, Wis.
8. The role of endocellular proteolytic enzymes during stages of caseation and softening.—Dr. Charles Weiss, Jewish Hospital, Philadelphia.
9. Investigation of some of the enzymatic factors involved in caseation of tuberculosis.—Dr. Donald E. Bowman, University of Indiana, Indianapolis. (This study is supported by funds contributed by the Indiana Tuberculosis Association and will be correlated with the previous study [No. 8].)
10. Study of vitamin metabolism in relation to growth of human and bovine type tubercle bacilli.—Dr. David T. Smith, Duke University, Durham, N. C.
11. Pathologic study of lobes and lungs removed surgically and available for histologic investigation.—Dr. William Meissner, N. E. Deaconess Hospital, Boston.
12. Tabulation of statistical results of: (a) Pregnancy and tuberculosis, (b) tuberculosis in nurses.—Dr. T. L. Badger, Boston City Hospital, Boston.
13. Provision of standard strains of tubercle bacilli whose history, virulence and, as far as possible, chemical structure is known.—Dr. Edward N. Packard, Saranac Lake Laboratory, Saranac Lake, N. Y.
14. Investigation of forces responsible for movement of air into and out of the lungs.—Dr. George W. Wright, Edward L. Trudeau Foundation, Saranac, N. Y.
15. Study of influence of posture on lung size.—Dr. George W. Wright, Edward L. Trudeau Foundation.
16. Determiation of best laboratory procedures for culture mediums.—Mr. William Steenken, Edward L. Trudeau Foundation; Dr. C. Richard Smith, Barlow Sanatorium, Los Angeles; Dr. M. I. Smith, National Institute of Health, U. S. Public Health Service, Bethesda, Md.
17. Study of minimal tuberculosis in nurses.—Dr. Carroll E. Palmer, National Institute of Health, Bethesda, Md.
18. Studies for the determination of the effectiveness of streptomycin in the treatment of tuberculosis.—A series of projects in cooperation with the National Institute of Health, Bethesda, Md.

NOTE: The following tuberculosis associations have contributed funds to the medical research program but have left the decision for their allocation to the National Tuberculosis Association: Pennsylvania Tuberculosis Society, Philadelphia, Philadelphia Tuberculosis and Health Association, Philadelphia, and Reading Tuberculosis Association, Reading, Pa.

Appoint Associate Director of National Health Council.—Dr. John W. Ferree, New York, formerly director, division of educational services, American Social Hygiene Association, has been appointed executive director of the National Health Council. He will be engaged principally in helping existing local, county and state health councils broaden the scope of their usefulness and in stimulating the formation of councils where their establishment would advance the effectiveness of community and state health agencies. Dr. Ferree received his medical degree from the Indiana University School of Medicine, Bloomington, and his Master of Public Health degree from Johns Hopkins University School of Public Health and Hygiene, Baltimore. He was chief of the bureau of local health administration, Indiana State Board of Health, 1936-1938, and from 1940 to 1942 he was state health commissioner for Indiana. After retiring from active duty with the Medical Corps, U. S. Navy, in 1945 with the rank of commander, Dr. Ferree joined the staff of the American Social Hygiene Association.

American Diabetes Association Meeting.—The annual meeting of the American Diabetes Association will be held, June 7-8, at the Chalfonte-Haddon Hall, Atlantic City, under the presidency of Dr. Russell M. Wilder, Rochester, Minn. Speakers on the program at 2 p. m. include Dr. Joseph Berkson, Mayo Clinic, Rochester, "Life Expectancy in Diabetes"; Drs. E. T. Waters, associate professor of physiology, and Charles H. Best, University of Toronto, "Importance of Developing an Accurate Method for Estimation of Insulin in the Blood"; Dr. Hugh L. C. Wilkerson, Boston, "Office of Diabetes, U. S. Public Health Service, Plans and Program"; Drs. Ferdinand R. Schemm, Felix H. Crago and John A. Layne, Great Falls (Montana) Clinic, "Control of Edema in Diabetic Patients with General Vascular Disease," and Dr. Geza de Takats, University of Illinois College of Medicine, Chicago, "Delayed Primary Suture in the Surgical Management of Diabetic Gangrene." At the banquet Sunday night the Banting Lecture will be delivered by Dr. George H. A. Clowes, Indianapolis, on "Development of Large Scale Production of Insulin."

CANADA

Survey of Milk Supplies.—In a recent survey in the eight provinces outside Ontario it was revealed that of the 366 municipalities represented only 13 per cent have compulsory pasteurization by-laws. Ontario was excluded because it is the only province which has a province-wide law in force. Of cities and towns in Saskatchewan 20 per cent reported safe milk by-laws; Quebec was second with 15 per cent; ninety municipalities, or 20 per cent, reported that their supply was unpasteurized; sixteen revealed that while they had no compulsory law their supply was 100 per cent pasteurized. Forty-one municipalities revealed that 90 per cent or more of their milk supply was pasteurized.

The Annual Meeting.—The Canadian Medical Association will hold its annual meeting June 23-27 in the Royal Alexandria Hotel, Winnipeg, under the presidency of Dr. Wallace Wilson, Vancouver. The program will consist of round table conferences to be held the mornings of June 25-27 and sectional meetings to be held the afternoons of those days. A panel discussion on the provision for medical care is being arranged for Thursday evening, June 26, by the committee on medical economics. Among the subjects of the round table conferences will be Management of Hypertension, Cesarean Section—Indications and Contraindications, and Management of Bulbar Poliomyelitis. Among the speakers will be Drs. Edgar J. Huenekens, Robert E. Priest and Abe B. Baker, all of Minneapolis. On Wednesday the Osler Lecture will be presented by Professor John M. McMichael, London, England, on "Osler: The Textbook and Medical Education." Among the speakers at the section meetings will be Dr. Paul A. O'Leary, Rochester, Minn., on "Recent Concepts of the Dermatoscleroses" in the section of dermatology; Dr. Warren H. Cole, Chicago, whose subject will be announced, in the section of surgery; Dr. Leo G. Rigler, Minneapolis, "Emphysema: An Early Sign of Bronchogenic Carcinoma" in the section of radiology, and Dr. E. Bruce Tovee, Chicago, "Present Status of Vagus Section in Ulceration of the Stomach and Duodenum" in the section of surgery.

Marriages

HAROLD H. KERR, Akron, Iowa, to Miss Norma Hayes Trabold of Wrightstown, Pa., in New York February 15.

WALTER K. HOFFMAN, Memphis, Tenn., to Mrs. Phyllis Benson Halladay of Oakland, Calif., January 25.

STEPHEN ABRAM GREENBERG, Florence, S. C., to Miss Ruth Barbara Brody in New York January 26.

BIRT L. BROWNING, Miami Beach, Fla., to Mrs. Bessie Hickman in Brunswick, Ga., Dec. 24, 1946.

JUNE U. GUNTER, Sanford, N. C., to Miss Elizabeth G. Kerr of Philadelphia February 1.

Deaths

Henry Hamilton Moore Lyle ⊕ New York; born in Connor County, Ulster Province, Ireland, Nov. 13, 1875; Columbia University College of Physicians and Surgeons, New York, 1900; professor of clinical surgery at the Cornell University Medical College; member of the American Surgical Association and the Society of Clinical Surgery; fellow of the American College [illegible] rseas during World War I and won the [illegible] Service Medal, the British War Medal, the British Victory Medal and other decorations; consulting surgeon, Stuyvesant Square Hospital and Veterans Administration, district number 2, in New York, Elizabeth A. Horton Memorial Hospital in Middletown, Cornwall Hospital in Cornwall, New York State Reconstruction Home for Children in West Haverstraw, St. Luke's Hospital in Newburgh and St. Luke's Hospital in New York, where he died March 11, aged 71, of coronary heart disease.

Lois Ellene Taylor, Belchertown, Mass.; born in Poultney, Vt., July 8, 1909; University of Vermont College of Medicine, Burlington, 1933; interned at the New England Hospital for Women and Children in Boston; served a residency at the Danvers State Hospital in Danvers and the Brattleboro Retreat in Brattleboro, Vt.; diplomate of the National Board of Medical Examiners; member of the New England Society of Psychiatry and the American Medical Association; lieutenant, senior grade, in the U. S. Naval Reserve during World War II; winner of the Sesquicentennial American Youth Award for 1926 and was presented with a gold medal by President Calvin Coolidge; since 1937 senior physician at the Belchertown State Hospital, where she died March 21, aged 37.

James E. King ⊕ Buffalo; born in Buffalo, Sept. 15, 1874; University of Buffalo School of Medicine, 1896; professor of gynecology emeritus at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology; member and past president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; past president of the Buffalo Academy of Medicine, Medical Society of Erie County and the University of Buffalo Alumni Association; fellow and formerly vice president of the American Gynecological Society; fellow of the International College of Surgeons and the American College of Surgeons; served on the staffs of the Buffalo General and the Edward J. Meyer Memorial hospitals; died March 9, aged 72, of heart disease.

William Sharp Lindsay, Topeka, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1874; member of the American Medical Association and in 1919 and 1920 member of the House of Delegates; served as president of the Kansas State Medical Society and the Shawnee County Medical Society; formerly dean and professor at the Kansas Medical College; at one time associated with the Topeka State Hospital, where he served as superintendent; formerly in charge of the Cottage for Mental and Nervous Diseases, Christ's Hospital; for many years trustee of the Washburn College; died February 20, aged 94, of heart disease.

Frank Edward Artaud ⊕ Major, U. S. Army, retired, Treasure Island, Fla.; Medical Department of Tulane University of Louisiana, New Orleans, 1884; member of the Medical Association of Georgia; veteran of the Spanish-American War and World War I; entered the regular army medical corps on March 15, 1927 as a first lieutenant; retired March 15, 1927 for disability in line of duty; promoted to major under the special retirement act of Congress for June 21, 1930; died in the Veterans Administration Hospital, Bay Pines, April 9, aged 87 of coronary sclerosis.

Wilbur Arthur Baker ⊕ Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1917; on the courtesy staff of the Menorah Hospital; died in Phoenix, Ariz., February 24, aged 54, of coronary thrombosis.

George Alexander Brandon, Jackson, Tenn.; University of Nashville Medical Department, 1906; member of the American Medical Association; affiliated with the Henderson County draft boards during World War I and World War II; died February 26, aged 72, of cerebral hemorrhage.

Jerry B. Callahan, Orlando, Fla.; Leonard Medical School, Raleigh, 1907; died February 28, aged 63, of coronary heart disease.

Robert Taylor Childress, Kingsport, Tenn. (licensed in Tennessee in 1911); served as chairman of the county school board; died February 22, aged 68, of hypertension.

Chester Cyril Coates, New York; Illinois Medical College, Chicago, 1899; died in St. Clare's Hospital February 10, aged 73.

Joseph Evan Crawford ⊕ Ruston, La.; Memphis (Tenn.) Hospital Medical College, 1907; on the staff of the Ruston-Lincoln Sanitarium, where he died February 17, aged 68, of cerebral hemorrhage.

George Byron Cross, Lakeville, Minn.; Chicago Homeopathic Medical College, 1901; died recently, aged 68, of cerebral thrombosis.

Frank C. Dildine, Port Jefferson, N. Y.; Baltimore Medical College, 1897; member of the American Medical Association; died February 17, aged 79, of accidental monoxide gas poisoning.

Theodore David Dockstader, Ravena, N. Y.; Albany Medical College, 1905; died February 13, aged 63, of multiple sclerosis.

Pressly Young Donald, Selma, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1915; member of the American Medical Association and the Southeastern Surgical Congress; past president of the Dallas County Medical Society; served during World War I; member of the city school board; chairman of the county board of health; on the staffs of the Good Samaritan Hospital and King Memorial Hospital, where he died February 26, aged 57, of acute gangrenous cholecystitis and cholelithiasis.

Joseph Koger Fairey, St. Matthews, S. C.; Medical College of the State of South Carolina, Charleston, 1891; member of the American Medical Association; died February 21, aged 78, of pneumonia.

David Ferguson Jr., ⊕ Medical Inspector, Commander, U. S. Navy, retired, *Milledgeville, Ga.*; Emory University School of Medicine, Atlanta, 1914; specialist certified by the American Board of Internal Medicine; entered the U. S. Navy *on Dec. 31, 1917* and retired Dec. 1, *1941* for incapacity resulting from an incident of the service; died Aug. 19, 1946, aged 53.

Emma Culross Gibbons, Portland, Maine; McGill University Faculty of Medicine, Montreal, Que., Canada, 1923; *died February* 16, aged 71, of coronary occlusion.

Vincent Jones Gragg ⊕ Magnolia Springs, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1908; for many years health officer of Chilton County; at one time mayor of Clanton; president of the Baldwin County Medical Society; member of the board of directors and served as president of the Central Alabama Hospital in Clanton; died in the Highland Avenue Baptist Hospital, Birmingham, February 17, aged 70, of intestinal obstruction.

Edwin Austin Hatch, Brooklyn; Long Island College Hospital, Brooklyn, 1881; member of the American Medical Association; formerly on the staff of St. Mary's Hospital; died recently, aged 91, of ruptured aneurysm and arteriosclerosis.

Jacob Roland Heller, Allentown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1928; member of the American Medical Association; medical examiner for the school district in Allentown; interned at the Allentown Hospital, where he served as a member of the staff; began active duty as a lieutenant commander in the U. S. Naval Reserve in October 1942; service terminated in March 1946 with the rank of commander; died February 2, aged 44, of coronary occlusion.

David Williams Henderson ⊕ Salt Lake City; *Jefferson* Medical College of Philadelphia, 1912; specialist certified by the American Board of Ophthalmology; *member of the Western* Ophthalmological Society and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; member of the staff of the Dr. W. H. Groves *Latter Day* Saints Hospital; died February 1, aged 65, of carcinoma.

Frederick Kingsley ⊕ Boston; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1905; for many years consultant at the Medfield (Mass.) State Hospital; died February 1, aged 66, of coronary thrombosis

John Raymond Lynch, New York; Fordham University School of Medicine, New York, 1915; member of the American Medical Association; served during World War I; died in the Fitch Sanitarium January 21, aged 54.

Jesse L. Macbeth ⊕ St. Clair, Minn.; Fort Wayne College of Medicine, 1905; died in St. Joseph's Hospital in Mankato recently, aged 66, of carcinoma.

John Tate McNabb, Trenton, Tenn.; University of Tennessee College of Medicine, Memphis, 1934; interned at the Baroness Erlanger Hospital, Pine Breeze Sanatorium and the Children's hospitals in Chattanooga; at one time assistant physician at the Eastern State Hospital in Knoxville; member of the American Medical Association; served during World War II; formerly associated with the U. S. Public Health Service Reserve; died in Monroe, La., April 9, 1946, aged 39, of chronic myocarditis while en route to Alexandria, La., to establish his practice.

M. Mozart Marrin, Grand Rapids, Mich.; University of Michigan Medical School, Ann Arbor, 1932; member of the American Medical Association; awarded the Edward and Susan Lowe medical fellowship for 1941; fellow of the American College of Surgeons; served during World War II; on the staff of the Butterworth Hospital, where he served an internship and where he died February 8, aged 40, of coronary thrombosis.

Joseph Alston Maxwell ⊕ Tuscaloosa, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1912; served during World War I; fellow of the American College of Surgeons; on the staffs of the Druid City and Stillman hospitals; died February 14, aged 59, of heart disease.

George Henry Musso, Lynn, Mass.; New York University Medical College, 1898; member of the American Medical Association; affiliated with the Union Hospital, where he died March 1, aged 72, of rupture of the aorta.

Louis Myer Piatt ⊕ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1923; specialist certified by the American Board of Radiology; affiliated with the Grant, St. Francis and Mercy hospitals; killed in an automobile accident March 2, aged 47, while returning from vacationing in Mexico.

Arnold Frederick Plankers, St. Paul; John A Creighton Medical College, Omaha, 1910; died in the Good Samaritan Hospital recently, aged 61, of coronary thrombosis and myocarditis.

Nathan Shapiro, Brooklyn; University of Edinburgh Faculty of Medicine, Scotland, 1930; member of the American Medical Association; on the staffs of the Coney Island and Israel Zion hospitals; died recently, aged 45.

Frank Ernest Sohler ⊕ Healdsburg, Calif.; Cooper Medical College, San Francisco, 1906; formerly on the staff of the French Hospital in San Francisco; died recently, aged 65.

William Joseph Topmoeller, Cincinnati; University of Cincinnati College of Medicine, 1912; cited for bravery and received the Purple Heart for services during World War I; affiliated with the Good Samaritan, Deaconess and Children's hospitals; past president of the Xavier College Alumni Association; died in the Holmes Hospital March 10, aged 57, of brain tumor.

Frank White Whitmore, St. Paul; Northwestern University Medical School, Chicago, 1915; member of the American Medical Association; clinical associate professor of nervous and mental diseases at the University of Minnesota Medical School; on the staffs of the Miller, St. Luke's, Ancker and Bethesda hospitals; died recently, aged 56, of aortic stenosis.

William Walter Wolf, Minneapolis; Hahnemann Medical College and Hospital of Philadelphia, 1939; member of the American Medical Association; served during World War II; affiliated with the Swedish and Deaconess hospitals; died Dec. 14, 1946, aged 35, of coronary thrombosis.

Lieut. Harold A. Kepnes (MC), U. S. N. R., 1911-1942

Major Philip Bress, M. C., A. U. S., 1908-1944

Major Carlo J. Marinello, M. C., A. U. S., 1915-1944

Alfred Scheyer, New York; Friedrich-Wilhelms-Universität Medizinische Fakultat, Berlin, Prussia, 1896; member of the American Medical Association; on the staffs of the Lutheran and Gotham hospitals; staff member, Westside Y. M. C. A.; died March 17, aged 73, of heart disease.

Stamatis Demosthenes Zaph ⊕ Los Angeles; Chicago College of Medicine and Surgery, 1917; member of the Illinois State Medical Society; formerly affiliated with the Woodlawn Hospital in Chicago; died in Chicago March 7, aged 63, of pulmonary thrombosis.

KILLED IN ACTION

Harold Arthur Kepnes, Chelsea, Mass.; Tufts College Medical School, Boston, 1939; diplomate of the National Board of Medical Examiners; interned at the Queens General Hospital in Jamaica, N. Y.; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on July 7, 1941; promoted to lieutenant; served with the First Marine Division; killed in action in Guadalcanal Nov. 3, 1942, aged 31.

Philip Bress, Jackson, Ky.; University of Virginia Department of Medicine, Charlottesville, 1931; member of the American Medical Association; interned at the Baltimore City Hospitals; served a residency at St. Joseph's Hospital in Baltimore, Methodist Episcopal Hospital in Fort Wayne, Ind, and the Mercy Hospital in Logan, W. Va ; major, medical corps, Army of the United States; prisoner of war of the Japanese; killed in the South China Sea Oct. 24, 1944, aged 36, when the ship on which he was being transported was sunk.

Carlo James Marinello, Buffalo; University of Buffalo School of Medicine, 1939; diplomate of the National Board of Medical Examiners; served an internship and residency at the Edward J. Meyer Memorial Hospital; entered the medical corps of the Army of the United States as a first lieutenant in October 1940; spent fourteen months in the Panama Canal Zone; promoted to major; organized the 52d Portable Surgical Hospital, serving as commanding officer; with General MacArthur in the initial invasion of the Philippines; wounded Dec. 24, 1944; died in Leyte, Philippine Islands, Dec. 31, 1944, aged 29.

Medical History in Postage Stamps

An exhibition illustrative of medical history in postage stamps, which appears to be the first of its kind in this country, was held at the Historical Section of the Royal Society of Medicine. It was accompanied with a demonstration on the epidiascope and a running commentary. Stamps of medical interest are of comparatively recent issue but have multiplied in the last twenty years. They can be divided into two classes: those bearing the portraits of medical men and those depicting medical scenes, such as hospitals and medical congresses. The first medical man to be depicted appears to have been F. Espejo of Ecuador in 1899. But the first man of eminence so honored was Boerhaave, whom the Netherlands commemorated in 1928, though France began a series in honor of Pasteur's work in 1923. Among other famous men commemorated are Vesalius, Paré, Haller, Semmelweis, Purkinje, Ramon y Cajal and Reed. Britain has been backward in this form of commemoration. Not until Sir Wilfred Grenfell was commemorated on a Newfoundland stamp in 1941 was any British medical man depicted.

Intelligence and Fertility: Are We Degenerating?

At the request of the Royal Commission on Population Sir Cyril Burt, professor of psychology, University College, London, has surveyed the evidence on the relation between fertility and intelligence, and has come to a most disquieting conclusion. In different sections of the community the birth rate shows wide differences. Using data obtained from surveys of the school population by means of intelligence tests, Burt has considered whether differences in the birth rate are likely to alter the inherited mental qualities of the nation. He has found that children of the poorer social classes have an intelligence nearly two years below that of children of the better social classes, while at the same time they are drawn from families nearly twice as large. More important than this is his conclusion that the average level of intelligence in the general population is declining. He claims that the decline during the past generation has amounted to about three or four "natal months" (meaning that the intelligence tests show that the children have reached only the level of those younger by that period). The prolongation of such a decline would gravely affect in time the mental status of the population. Thus, if the rate assumed continues, in a little over fifty years the number of pupils of scholarship ability would be approximately halved and the number of feebleminded would be doubled.

Another point made by Burt is that in the numerous working class it is the more intelligent families who contribute fewest to the next generation. In general the larger the family the lower the level of intelligence; the smaller, the more intelligent the parents. These conclusions are so important that the need for further investigation is suggested. They are certainly open to some question. An offset to the higher birth rate of the less intelligent is their higher death rate. It is well known that throughout the living world the lower the organism the greater the powers of multiplication, but that has never meant the swamping of the higher forms of life by the lower, for there are countervailing forces, and so evolution has not been prevented. Herbert Spencer long ago emphasized as fundamental the antagonism between individuation and genesis. "Every higher degree of individual evolution is followed by a lower degree of race multiplication, and vice versa."

Fatal Failure to Remove a Tourniquet

An unusual case of negligence is reported as having occurred in the hospital of the large Lancashire manufacturing town of Oldham. A man aged 53, a head carder in a cotton mill, was admitted for a plastic bone operation, which consisted in removal of a piece of bone from the right leg for grafting on the right wrist. The operation was duly performed but he was returned to bed without removal of a tourniquet which had been placed on the leg. This was allowed to remain on eleven hours, although he was in great agony and complained to the nurse that there was something tight on his leg. His complaint was not investigated until he became worse. His condition became so critical that blood transfusion was performed. He collapsed and died.

His widow entered suit for damages against the hospital and the two surgeons who performed the operation. In court their lawyer said that he admitted the liability of the defendants and that it remained only for the judge to assess damages. The judge awarded $16,000 damages and costs against the hospital and the two surgeons who performed the operation. He said that he would not comment on the sorrow which had been caused, but it was a little surprising that the tourniquet had been left on. So far no explanation has been given of this apparently unprecedented mistake. But it may be surmised that it is not unconnected with two phenomena of the postwar period—overworked surgeons and shortage of nurses involving the placing of the partially trained in too responsible positions.

ITALY

(From Our Regular Correspondent)

April 26, 1947.

Center for Studies on Antibiotics

A center for information and studies on antibiotics has been established in Milan; Professor Alexander Fleming was nominated honorary president at the opening session. Professor Carlinfanti will act as director, with Dr. G. Pauletta as technical secretary. It is the aim of the center to support and to coordinate the forces of Italian research in the field of antibiotics. For the achievement of this aim the center will promote research on antibiotic substances by supporting Italian biologists, clinicians and chemists in carrying out and publishing reports of their work and by furnishing current literature, coordinate antibiotic research in Italy by favoring collaboration between research workers, by advice concerning methods of study, by furnishing research material and by the distribution of prizes. The center will answer questions of medical practitioners concerning antibiotics, organize lectures and conferences, publish the transactions and inform other countries of the contributions of Italian scholars to the subject. The Centro Italiano Informazioni Studi Antibiotici (Italian Information Center on Antibiotic Studies) is located at Corso Concordia No. 9, Milan.

International Congress on Reproduction

The first international congress on physiopathology of reproduction and of artificial fecundation will be held in Milan in April 1948 on the initiative of the Experimental Institute "Lazzaro Spallanzani" with the support of the University of Milan. The scientific objects of the institute are of interest to all countries of the world. The preparatory committee of the congress consists of biologists, geneticists, pathologists, gynecologists and zootechnicians and of representatives of various governmental departments. The rector of the University of Milan has been nominated as honorary president. The secretary general of the congress has his headquarters near the Institute Lazzaro Spallanzani, Via Bonzetti 17, Milan.

Association of Volunteer Blood Donors

The council of directors of the National Association of Volunteer Blood Donors, at a meeting in Bergamo, discussed the democratization of the former community organizations and establishment of new associations in places which have been deprived of an efficient transfusion service, provisions for safeguarding donors, provisions in the field of assistance, insurance and food supply, and suggestions for sanctions in order to prevent abuses. The council has asked the government for urgent recognition of the association to give more authority to the association and to improve the position of the volunteer blood donors.

Convention of Gastroenterologists

At the convention in Florence of practitioners specializing in diseases of the stomach and intestine those attending favored expanding the Italian Association of Gastroenterologists to include the problems of nutrition. At the meeting in Bologna in the spring reports will be presented on megaesophagus by Pieri-Bonadies and by Basso and on duodenitis, with the exception of duodenal ulcers, by Gasbarrini and by Di Gaetano.

OSLO

(From Our Regular Correspondent)

April 26, 1947.

Methyl Alcohol Poisoning

During the war several outbreaks of methyl alcohol (methanol) poisoning occurred in persons endowed with greater thirst than discrimination in the choice of their drinks. The patients were rushed to hospitals in or near Oslo, where they came under the enterprising observation of Dr. Oluf Röe, a young ophthalmologist. He has just published a 253 page study of the subject, on which he throws light calculated to promote research on new lines. Certain earlier teachings have hinged on experiments on animals, but Röe came to the conclusion that a fundamental difference probably exists between man and beast in this respect. His material consists of 82 patients treated in seven different hospitals. As many as 48 patients suffered from severe acidosis on admission to the hospital, and Röe has found that, whatever the reaction of experimental animals, in human beings at any rate the outcome of methanol poisoning depends entirely on the degree of acidosis. Hence his advocacy of bicarbonate treatment. His studies of the antecedents of his patients have led to the conclusion that ethyl alcohol counteracts methyl alcohol, a low concentration of the former in the blood being sufficient to prevent acidosis even when the concentration of the latter is high. Röe reviews (and dismisses as unconvincing) the hitherto commonly accepted notion that individual predisposition plays an important part in methanol poisoning.

The Prophylaxis of Dental Caries

It was only by chance that your correspondent found and was then intrigued by a communication by Professor G. Toverud on the prophylaxis of dental caries in the *Odontologisk Tidskrift* (1946, No. 3). For here, in only eighteen pages packed with tables and charts, is a comprehensive review of the recent research by Professor Toverud and his staff. Some of this research was started in 1936 and was voluntary; some depended on war conditions and was therefore more or less involuntary. It is suggested that all the research workers in this field should get together and study the behavior of dental caries during World War II—one of the greatest experiments in nutrition in the history of mankind. To those who are tempted to explain dental caries as an easily understood deficiency disease preventable and curable by the dietary of our primitive ancestors, Professor Toverud addresses a timely warning. In his opinion this disease is the outcome of the complex interplay of many factors about which we have still much to learn.

BRAZIL

(From Our Regular Correspondent)

Rio de Janeiro, April 26, 1947.

Active Rheumatic Carditis in Cardiac Failure

Rheumatism is considered in Brazil a relatively minor factor in the etiology of heart lesions, owing to the warm climate and the high incidence of syphilis in the population. Dr. Jairo Ramos, professor at the Paulista School of Medicine, São Paulo, has published a paper on cardiac failure in young patients through the involvement of the myocardium by an active rheumatic process. The report includes the analysis of 400 cases of acute and chronic cardiac rheumatism, among which 89 cases of rheumatic carditis were discovered (22.25 per cent). The criterion for the clinical diagnosis was to consider as rheumatic carditis the cases presenting simultaneously the largest number of signs of active rheumatism, particularly when the age was over 30 years. The age distribution in the 89 cases of active rheumatic carditis was 0-9 years 22 cases, 10-19 years 43, 20-29 years 17, 30-39 years 6, 40-49 years 1. The incidence of active rheumatic carditis within each ten year age group among the 400 cases of cardiac rheumatism varied: 0-9 years 22 out of 33, 10-19 years 43 out of 104, 20-29 years 17 out of 88, 30-39 years 6 out of 88, 40-49 years 1 out of 53, 50-59 years 0 out of 21. According to these figures the highest incidence of active rheumatic carditis occurs in young patients, a fact which is in accordance with the data in the medical literature of Europe and the United States Below 20 years of age more than half the patients with cardiac rheumatism present clinically active rheumatic carditis; above 40 years the condition is practically nonexistent.

Influence of Variation of Cellular Permeability on Immunity

Dr. F. da Rocha Lagoa of the Oswaldo Cruz Institute, Rio de Janeiro, recently completed studies on the influence of the variation of cellular permeability on the organic resistance to infections. He used three groups of substances. The first group comprised substances that increase the permeability—testosterone, acetylcholine and the diffusion factor of staphylococcus as demonstrated by Viale, McClean, Okamoto, Gellhorn and Duran-Reynals. The second group comprised substances that decrease the cellular permeability—atropine, epinephrine and calcium as demonstrated by Okamoto, Gellhorn and Voloskov. The third group was represented by adrenal cortex extract, which maintains without variation the cellular permeability, as recently demonstrated by Rauschschwalbe and by Cicardo. The author used synthetic testosterone propionate, acetylcholine Roche and Eschatin Parke-Davis. To ascertain the resistance to infections, several hundred adult mice were infected with sufficient amounts of Klebsiella pneumoniae, Pseudomonas aeruginosa, Salmonella enteritidis and Diplococcus pneumoniae. Adult rabbits were used for the determination of the production of antibodies (hemolysins, precipitins and agglutinins).

His main conclusions are that cellular permeability plays an important part in the development of infections. Substances that increase the permeability contribute to the development of infections; substances that decrease the permeability have no disclosed influence on the course of infections; substances which contribute to maintain the normal cellular permeability increase the resistance to infections. The substances that have been studied as modifying or not the cellular permeability do not exercise any influence worth mentioning on the formation of hemolysins, agglutinins and precipitins.

Correspondence

FATAL ALLERGIC REACTION DUE TO INFLUENZA VACCINE

To the Editor:—In the article with this title by Dr. Theodore J. Curphey in The Journal, April 12, the death described was, in my opinion, not due to the egg but to sensitivity to the bacteria of the vaccine. Egg allergies in children produce definite skin or other evidences of sensitivities with which parents are familiar and which they delete from their diets. Even a positive skin test would not definitely establish the cause as due to egg, because this patient had been having egg without symptoms.

In favor of bacterial allergy is the history of aspirin sensitivity, which, in my experience, is frequently a concomitant of bacterial sensitivity. I have seen small doses of catarrhal vaccine produce symptoms approaching the description of this fatal case, and for this reason we commence all our vaccine therapy with dilutions. For example, a supervising nurse at one of our allergy clinics was started with a dilution of 1 : 1,000,000, 0.02 cc., because a 1 : 10 dilution originally produced a violent constitutional symptom. A disabled policeman with asthma almost died with symptoms similar to those described in Dr. Curphey's case from a small dose of catarrhal vaccine; he too was sensitive to aspirin.

Although an intracutaneous test for egg sensitivity may throw some light on a case within twenty minutes, bacterial allergy cannot be diagnosed by skin tests alone.

The answer to the problem may be eased by not giving influenza vaccine *in one dose. Three or more ascending doses* are advisable; if there is a history of aspirin sensitivity the vaccine should not be used, but if it appears necessary epinephrine hydrochloride 1 : 1,000 should be injected twenty minutes before and an ephedrine phenobarbital combination should be given every four hours after the injection for at least three days (Serum Administration and Allergy, Queries and Minor Notes, The Journal, May 20, 1944, p. 238).

David Louis Engelsher, M D., New York.

ECLAMPSIA

To the Editor:—In connection with the "Contribution to the Study of Eclampsia" by Whitacre, Loeb and Chin in The Journal, February 15, may I draw your attention to the publication "Protein Depletion in Pregnancy Toxemia" in the *Western Journal of Surgery, Obstetric and Gynecology* (**54:** 392 [Oct.] 1946). The main sequence in eclampsia is (1) fetal demand for maternal protein, aggravated by inadequate protein intake, (2) hypoalbuminemia, (3) hypoproteinemic cerebral edema, (4) increased intracranial pressure and (5) elevation of blood pressure. There are many side effects complicating the picture. Changes in the kidneys are secondary and may be partly responsible for the high blood pressure. The important cause of the elevation of blood pressure in eclampsia is the increase in intracranial pressure. Hypoalbuminemia is a constant finding in pregnancy toxemia.

H. Spitzer, M.D , Curaçao, NWI.

HEPATIC IMPAIRMENT

To the Editor:—A number of questions arise when one reads the article by Mateer and his associates on hepatic impairment in The Journal, March 29. Their use of screening liver function tests in over 300 healthy individuals resulted in designating about 20 per cent as cases of "subclinical liver impairment." In the absence of exposure to known toxins or infectious agents this percentage appears high. Assuming that this group contains no false positives, what proportion may be expected to emerge as clinical hepatopathies? Has a control group of patients positive to liver function tests who have not had a therapeutic test been followed? What percentage of these show subsequent negative function tests?

On the other hand, in the presence of so many false negatives both in clinical and in subclinical liver disease, may not many so-called subclinical cases be false positives? The intangibles involved in studying a subclinical disease entity must be tremendous, especially when utilizing laboratory tests whose exact mechanisms are not well understood.

Sidney Cohen, M.D.,
Wadsworth General Hospital,
Los Angeles.

TRANSFUSION MALARIA

To the Editor:—I was interested in reading the letter from Dr. Coggeshall on the danger of transfusion malaria which appeared in the April 19 issue of The Journal. It is well known, of course, that there is a risk of malaria developing in the recipient when blood is used from a donor who has had malaria within the past few or several years, even though the blood may have been stored in a blood bank for a period of days. However, I believe one should not overemphasize the danger of transfusion malaria, because it is easily controlled, and one should not hesitate to use, in the face of an emergency, a donor who has had malaria even recently. In such a case, either the donor or the recipient should be treated with atabrine or chloroquin, which would most certainly prevent the development of malaria in the recipient. Furthermore, transfusion malaria, being trophozoite induced, does not give rise to "exoerythrocytic forms." Hence, relapses do not occur.

George M. Saunders, M.D., St. Louis.
Assistant Professor of Preventive Medicine, Washington University School of Medicine.

"MUMPSIMUS"

To the Editor:—I noticed that in The Journal, Dec. 14, 1946, you commented on John Forbes's article Myth and Mumpsimus and gave a meaningless explanation (though correct) of the derivation of mumpsimus.

To give the person, tense and mood of the verb *sumo,* from which sumpsimus was corrupted, gives no clue to the meaning whatsoever.

The explanation is that an illiterate English priest, when corrected for reading "Quod in ore mumpsimus" in The Mass, replied "I will not change my old mumpsimus for your new sumpsimus." This story originally came out in R. Pace De Fructu 1517, page 80—but maybe you have not had access to this reference. You can check this in the New English Dictionary or Ivor Brown's book "Just Another Word."

Richard Asher, M.D., M.R.C.P.

Great Portland Street,
London, W. 1., England.

DISSOLUTION OF TEETH BY LEMON JUICE

To the Editor:—The editorial comment on "Dissolution of Substance of Teeth by Lemon Juice" in the March 19 issue of The Journal is of great interest. However, it should be noted that this observation was first made by S. C. Miller of New York University College of Dentistry in 1935 and commented on in an editorial in *Dental Items of Interest* in October 1935. It is also discussed in Dr. Miller's Oral Diagnosis and Treatment (Philadelphia, Blakiston Company, 1936, p. 263; 1946, p. 367) and his Textbook of Periodontia (1938, p. 433; 1943, p. 61).

Morris Warren, D.D.S., New York.

MEDICOLEGAL ABSTRACTS

Dentists: Extraction of Sixteen Teeth Not Necessarily Negligence.—The plaintiff sued for damages for the death of her husband allegedly caused by the negligence of the defendant dentist From a judgment of no cause of action, the plaintiff appealed to the Supreme Court of Michigan

The plaintiff's husband went to the office of the defendant dentist for the purpose of having sixteen upper teeth extracted Twenty minutes later he was dead, after having been administered gas as an anesthetic At the trial the defendant was not asked, nor did he state, how many teeth were actually extracted or how the death occurred A physician testified that he had examined the deceased's heart not long before and found it normal In this physician's opinion, the greater the number of teeth extracted, the greater the shock to the system, but in answer to a hypothetical question he said that the death could have resulted from any one of a number of causes

Considering the evidence in the light most favorable to the plaintiff, can it be said that the deceased's death resulted from the surgical shock following the extraction of sixteen teeth or from the improper administration of gas, asked the court? In a prior Michigan case (*Voss v Adams,* 271 Mich 203, 259 N W 889) there was testimony to the effect that, according to local standards, it was not proper practice to extract more than eight teeth at one sitting because of the increased danger of surgical shock and the increased infection let loose in the system In the instant case, said the court, there was no testimony in the record as to the standard practice in the locality and no showing of the cause of death The mere proof that sixteen teeth had been extracted at one sitting in the absence of testimony showing that this was not the usual and ordinary practice of dentists in the locality, is not, in and of itself, sufficient to establish negligence, added the court Plaintiff had the burden of showing that her husband's death was brought about by the defendant's failure to exercise the reasonable and ordinary care, skill and diligence possessed by others in the same line of practice and work in similar localities We are compelled, concluded the Supreme Court, to agree with the trial judge that the plaintiff failed to establish negligence on the part of the defendant Accordingly the judgment in favor of the defendant was affirmed—*Nemec v Green, 25 N W (2d) 20 (Mich, 1946)*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Congestive Heart Failure and Death in Case of Paroxysmal Auricular Tachycardia: Case Report. R. P. Grant.—p. 121.

Fatal Coronary Artery Disease in Young Men.—Coronary artery disease is not generally believed to be a frequent cause of death below the age of 40. Nine instances reported by Poe from the records of one army hospital comprised 7.4 per cent of all necropsies, a total of 121, performed on men between the ages of 18 and 40 years who died of natural causes. Few of these 9 young men gave evidence of having had symptoms of coronary disease before the fatal episode. Death was sudden and unheralded. Most of the 9 young men were of average or below average height. The weight of the heart did not reflect the seriousness of the cardiac condition. Slight to moderate enlargement of the liver may have been related to the heart disease. Evidence of old myocardial injury was frequent. Evidence of fresh infarction is rare in young men dying of coronary artery disease.

Effect of Overdose of Epinephrine.—McGinty and Baer report observations on a naval aviator who was inadvertently given an intramuscular injection of 5 cc. of a 1 : 1,000 solution of epinephrine hydrochloride. The arrhythmia noted in the first thirty minutes could have been due to frequent extrasystoles or to transient ventricular fibrillation. The precordial distress, the transient elevation of temperature, the increase of sedimentation rate and the prolonged electrocardiographic changes could have been due to actual infarction of the myocardium. The evidence in this case indicates that epinephrine in large doses causes relative coronary insufficiency in the normal adult.

Large Overdose of Epinephrine.—Horwitz observed a patient with urticaria who was given by mistake an intramuscular injection of 7 cc. of a 1 : 1,000 solution of epinephrine. There were no alarming immediate or late effects. There was no excessive perspiration and no cardiac arrhythmia other than a mild tachycardia. The highest blood pressure recorded was 220/96. The pulse rate reached 128 per minute. The epinephrine must have caused considerable angiospasm at the site of injection, thereby allowing itself to be absorbed slowly by the systemic circulation.

Congenital Heart Block Diagnosed in Utero.—Jordan and Randolph report that, because the fetal heart sounds five weeks before term were extremely slow, it was thought that the life of the fetus was in danger; but after observation for several hours with no change in the heart rate no attempt was made to induce labor. During the subsequent ten days the fetal heart rate was always between 40 and 46 per minute. Sound tracings of the fetal heart were made simultaneously with the maternal electrocardiogram. The mother was delivered at the beginning of the ninth month. The baby was an apparently healthy infant weighing 5 pounds 12 ounces (2,608 Gm.). Since birth the infant has presented a difficult feeding problem. Regurgitation of food is still frequent, yet fairly normal growth has taken place.

Respiratory Patterns in Pulmonary Tuberculosis. M. N. Rao and L. Silverman.—p. 574.

Cytology of Bronchial Secretions in Pulmonary Tuberculosis.—Herbut and Clerf state that a presumptive diagnosis of pulmonary tuberculosis can be made from a cytologic study of smears made of bronchoscopically removed secretions and stained by the Papanicolaou technic. Rounded clusters of ciliated epithelial cells, single ballooned and vacuolated ciliated epithelial cells and giant cells of the Langhans type are of importance in the diagnosis of tuberculosis. The author describes the technic employed in preparing the smears and presents cases in which this procedure proved helpful. The method is of particular value in differentiating pulmonary tuberculosis from carcinoma in patients in whom the lesions are atypically situated, in whom there is little constitutional disturbance and in whom repeated examination of sputum fails to reveal tubercle bacilli.

Effects of Streptomycin on Mycobacteria in Vitro.—Middlebrook and Yegian describe the composition and preparation of the "Tween 80" medium, which is a liquid synthetic medium in which mycobacteria grow more rapidly and more diffusely than in the conventional mediums. Freshly isolated tubercle bacilli from patients with pulmonary tuberculosis appear to have a uniform susceptibility to streptomycin in vitro. Exposure of tubercle bacilli to streptomycin in relatively low concentration in vitro inhibits subsequent multiplication of multiplying but not of nonmultiplying tubercle bacilli when they are transferred to medium free of streptomycin. All mycobacteria thus far tested develop resistance to streptomycin in vitro at a rapid rate. Resistance to streptomycin persists for at least four months and appears not to be paralleled by diminution in virulence for guinea pigs. The acquisition of resistance of mycobacteria to streptomycin is independent of their acquisition of resistance to a sulfonamide (or a sulfonamide-like agent), and the development of resistance to these drugs is retarded when mycobacteria are exposed to the two types of agents simultaneously.

Penicillin in Acute Bacterial Endocarditis.—Eight patients who had acute bacterial endocarditis were treated by Wilhelm and her associates with penicillin. Five patients died, the diagnosis being confirmed by necropsy. The clinical course of the 3 patients who recovered satisfied the criteria established for the diagnosis of this disease. The 3 patients who recovered had staphylococcic endocarditis, while of the 5 who died 4 had staphylococcic and 1 had pneumococcic endocarditis. The only hope in this disease lies in early diagnosis and vigorous treatment. Of the 5 patients who died, 4 probably were inadequately treated. The diagnosis was established late in the course of the disease in 3 of these patients, so that penicillin had been administered for two days or less before death. Whenever possible, the sensitivity of the causative organism should be determined and the dose of penicillin established accordingly. If the sensitivity of the organism to penicillin has not been determined, doses of 500,000 units per day should be given.

Cardiac Arrhythmias Complicating Pneumonectomy.—In an analysis of 120 patients undergoing total lung resection, Massie and Valle found that 11 developed arrhythmia of sufficient severity to have endangered the outcome of the operation or at least to have caused symptomatic difficulty. The arrhythmias included 5 instances of auricular fibrillation, 4 of auricular flutter and 1 each of frequent auricular and ventricular extrasystoles. The reason for the high incidence of arrhythmias following pneumonectomy could not be definitely determined. It is suggested that anoxemia and vagal stimulation may act synergistically in the production of these abnormal cardiac rhythms. Constant observation must be maintained for early recognition of the occurrence of abnormal cardiac rhythms. Treatment should be directed primarily to the attainment of prompt restoration of a normal sinus rhythm, and this result may be most often accomplished by rapid intravenous digitalization.

Epidemic of Trichinosis.—Hathaway and Blaney studied an epidemic of trichinosis among 587 German prisoners of war. Eighty-three were observed in the hospital; 437 who were not hospitalized had blood smears taken approximately one week after the last improperly prepared meal. The presence of eosinophilia in a high percentage of the men not hospitalized suggested the presence of trichinosis in a mild or subclinical form in 100 men. The exact date the trichinous meat was served cannot be determined, but sausage had been generally served uncooked. The typical clinical picture was characterized by a sudden onset of chilliness, fever, malaise and frontal headache. Associated with these complaints or occurring shortly afterward there was puffiness of the eyelids, which generally lasted three to five days. In most instances muscle pain, or muscle pain with tenderness, occurred a few days later but had disappeared or diminished considerably at the time of discharge. The average hospital stay was twenty-six days. The most significant laboratory finding was eosinophilia, which ranged as high as 61 per cent. The fact that this epidemic resulted after the ingestion of meat from reliable packers indicates that all pork products, regardless of the source, are potentially dangerous from the standpoint of trichinosis if served improperly cooked.

Pleuropulmonary Tularemia.—Hunt says that, during the period of the study of streptomycin therapy conducted in Nashville hospitals from April to September 1946, 15 cases of pleuropulmonary tularemia were encountered. Twelve of these patients were treated with streptomycin. The patients showed a prompt clinical response to small doses of the antibiotic. The rapid disappearance of Pasteurella tularensis from the sputum or pleural fluid, as determined by animal inoculation, indicated that the organism was rapidly killed in the tissues. The regression of pulmonic lesions and the healing of primary ulcers were believed to have been accelerated by streptomycin treatment but required a longer time interval than did clinical recovery. All the patients presented a rise in serum agglutinin titer after treatment. This increase in the serum agglutinin level may have resulted from the antigenic stimulus provided by the destruction of large numbers of organisms. Because of the diagnostic difficulties presented by many cases of tularemic pneumonia and the prompt response of tularemia to streptomycin therapy, the value of a therapeutic trial with this antibiotic in severe pneumonia of undetermined origin in areas in which tularemia is endemic is apparent.

Typhoid in Laboratory Workers.—Of the 4 patients studied by Haedicke 2 acquired the disease while working in the typhoid vaccine laboratory at the Army Medical School. These 2 patients worked with material containing 35 billion typhoid bacilli per cubic centimeter. The other 2 patients acquired their infection in the typhoid research division of the Army Medical School. There was no accident to which these infections could be attributed. These patients had all received at least one complete series of typhoid vaccine prior to the onset of their illness. No relationship was found to exist between the date of the last immunization and the date of onset of the disease. The interval varied from twenty-eight days to eleven months. The diagnosis was difficult in all cases because of the absence of the usual signs and symptoms. The clinical course was less severe than that usually seen in persons who have not been vaccinated. All patients were only mildly ill. The average length of time during which the temperature was elevated was five and a half weeks. There were no complications.

Cardiopulmonary Function After Pneumonectomy.—Cournand and his co-workers followed through the period of growth the cardiopulmonary function of 4 patients who had undergone pneumonectomy during childhood or early adolescence. They studied at regular intervals the lung volumes, the ventilatory efficiency of the chest bellows, the efficiency of alveolar ventilation and the state of respiratory gas exchange in the lung and in the arterial blood at rest and during exercise. The right ventricular pressures and the pulmonary blood flow were measured in 3 of the 4 subjects. In 2 patients who developed moderate pulmonary distention the only significant observations were a reduction in breathing reserve and severe oxygen unsaturation in the arterial blood during strenuous exercise. The moderate degree of pulmonary distention, which increased slightly in 1 subject during growth of the lung, has not progressed during the last three years. One subject without pulmonary distention had the same performance as a normal person. No significant hypertension has developed in the lesser circulation.

Surgical Treatment of Myasthenia Gravis.—This report by Clagett and Eaton of the Mayo Clinic is based on a series of 32 patients with myasthenia gravis who have been followed for six or more months since operation on the thymus gland. The entire series consisted of 191 patients, 159 of whom were not operated on. In 15 of the 32 cases thymic tumors were found at operation. In all but 1 of the remaining 17 a good sized thymus gland was found and removed. The authors believe that the results to date warrant thymic exploration in all cases of myasthenia gravis in which the disease is severe or progressive and in which the condition will permit surgery. The sternum splitting approach offers the best exposure in most instances.

Glomus Tumors.—Meyerding and Varney point out that glomus enlargements, or arteriovenous shunts, occur normally in skin and subcutaneous tissue. They occur most frequently in the finger tips. With increased growth of these tumors they become excruciatingly painful. They are usually located under the nail. Because of their rarity they may remain unrecognized for years. The authors have operated on 2 patients who had glomus tumors of nine and sixteen years' duration respectively. In each case there was a complete relief of symptoms. Early diagnosis and eradication are dependent on the recognition of the lesion by the general practitioner.

*Dissolution of Staghorn Calculus in Kidney Pelvis by Intermittent Irrigation with Solution G. J. J. Cordonnier.—p. 179.
Ear Canal Infections. O. J. Dixon.—p. 181.

Dissolution of Staghorn Calculus with Solution G.—Cordonnier says that solution G is a combination of citric acid, magnesium oxide and sodium carbonate in water. In view of the technical difficulty of a second operation on the left side of a woman aged 26 and the relatively poor condition of the right kidney, it was felt that dissolution of the left renal calculus should be attempted. Two number 6 F. catheters were passed to the kidney pelvis and left in place. Continuous irrigation with solution G was instituted. At the end of thirty-six hours the patient developed severe renal colic, gross hematuria and fever, and irrigations were discontinued. She then was placed on an acidification regimen using ammonium chloride, for two months. After this period the stone appeared less dense. The same procedure was followed as before, and irrigations with solution G were maintained for one hundred and twenty hours, when pain, fever and gross hematuria again prevented further treatment. At this time a great deal of the stone was found to have disappeared. She was again discharged on an acidification regimen and returned after one month, at which time the shadow in the pelvis was found to have disappeared.

*Chromaffin Tissue Tumors and Associated Paroxysmal Hypertension. H O. Schneider.—p. 216.

Chromaffin Tissue Tumors and Paroxysmal Hypertension.—A man aged 41 complained of attacks of faintness, flushing, palpitation and a choking sensation whenever stooping over. The only abnormal finding was a firm, smooth mass in the right upper abdominal quadrant. The patient complained of his presenting symptoms while the mass was being palpated. He became pale, restless and apprehensive. The pulse rate increased from 72 to 144 per minute. Blood pressure was 210/130. All symptoms and abnormal findings shortly returned to normal after the abdominal examination was completed These findings could be produced repeatedly by this manipulation. At operation a large tumor was found located in the region of the mesenteric ganglions. The tumor was removed The pathologic diagnosis was benign paraganglioma. Since his discharge from the hospital the patient has remained symptom free and has no evidence of hypertension Schneider reports this case of a palpable intra-abdominal chromaffin tissue tumor to focus attention on the possible existence of such tumors in the presence of hypertension.

Chemotherapy of Filariasis Bancrofti.—Culbertson and his associates summarize the results of a study designed to discover chemotherapeutic agents effective in filariasis bancrofti Preliminary tests were conducted on a naturally occurring filariasis (Litomosoides carinii) in the cotton rat. One hundred and fourteen patients with filariasis bancrofti have been treated with various drugs, 35 being treated with neostibosan, 11 with neostam, 6 with urea stibamine, 5 with stibanose, 15 with fuadin, 20 with anthiomaline, 4 with antimony and potassium tartrate and 18 with melarsen oxide. Fifteen patients have been left untreated to serve as a control group . Filariasis bancrofti can be eliminated from patients by the administration of certain compounds of antimony or arsenic.. The pentavalent antimonial neostibosan shows the greatest promise because it exerts a strong antagonistic effect on the filarial worm and can be used with comparative safety, being well tolerated by all subjects

Treatment of Malignant Tumors of Testes.—Kelby and Stenstrom analyzed 100 cases of malignant tumors of the testes observed at the University of Minnesota Hospitals from 1926 to 1943 inclusive. The group consisted of 34 unclassified cases, 37 seminomas and 29 carcinomatous mixed tumors. Metastasis was known to be present before irradiation was started in 65 per cent of the seminomas, 86 per cent of the carcinomatous mixed tumors and 70 per cent of the unclassified group. Therapy consisted in simple orchiectomy and irradiation in 90 cases, irradiation alone in 6 advanced cases and Hinman's operation and irradiation in 4 cases. In seminomas of the testis the five year survival rate is 56 per cent. In the carcinomatous mixed tumor group only 1 patient survived five years, while in the unclassified group 29 per cent survived five years. A five year survival rate of 29 per cent was obtained in all the patients with malignant testicular tumors considered together.

*Pellagrous Encephalopathy. P. R. Graves.—p. 253.

Pink Disease.—Fisher reviews the histories of 65 patients who attended the outpatient clinic at the Royal Manchester Children's Hospital during the fourteen years from 1932 to 1945. The average duration in the infants recovering from pink disease was four months. The disease develops insidiously and is usually well established when the infant enters the hospital. There are three basic symptoms: a profound change in temperament, muscular hypotonia and tachycardia. Muscular hypotonia may be extreme. The art of walking, if already attained, is lost. The cutaneous symptoms include the vasomotor phenomena of the extremities, the rash, excessive perspiration and the special manifestations affecting the buccal and conjunctival mucous membranes. The puffy, pink or bluish red, cold, clammy hands and feet and the sudaminal eruption on the trunk and limbs, crisscrossed by excoriation from scratching, are the two most regularly appearing features. There were 9 deaths in this series. The precise cause of the disease is unknown and treatment has been symptomatic, with special emphasis on prevention of secondary infections. Home nursing is the method of choice. A high vitamin intake has been advised as a measure of protection against superimposed infection. The main principles in management are scrupulous attention to bodily hygiene, particularly when desquamation is in process, segregation from any human source of nasopharyngeal or respiratory infection, and patience in feeding. All food should be boiled or cooked and served as cold as possible.

Pellagrous Encephalopathy.—Graves describes a deficiency syndrome which was present among prisoners of war in Singapore. The clinical manifestations suggested a brain lesion: the only pathologic support for this contention was the naked-eye appearances of the brain and spinal cord at the necropsies in the fatal cases. No microscopic examination was possible. The syndrome occurred in the form of a comparatively small outbreak after large epidemics of vitamin B_1 deficiency resulting in neuritic and edematous beriberi and Wernicke's encephalopathy and later epidemics of B_2 complex deficiencies giving rise to angular stomatitis, glossitis, scrotal dermatitis, pellagra, dermal lesions, retrobulbar neuritis and the painful foot syndrome. The observations presented in this paper are based on 63 cases, of which 6 were fatal. When severe, this condition is responsible for widespread disorder of cerebral function resulting in disturbance of memory, coma with quadriplegic rigidity characteristic of a decorticate animal, and in some cases convulsions. As recovery occurred spastic paraplegia was the common residual state. In minor disorders less evidence of the initial cerebral illness may yet be followed by a crippling spastic paraplegia or a lesser degree of spastic weakness. Complete recovery may ensue after a severe initial onset.

Thyroidectomy and Thiouracil in Toxic Goiter.—Himsworth and his associates assess the relative values of thyroidectomy and thiouracil. Sixty-five cases of toxic goiter that were treated with the thiouracil series of drugs were followed for periods of up to thirty months and compared with 93 cases treated with subtotal thyroidectomy. The reduction in pulse rate and basal metabolic rate during the first three weeks of treatment with thiouracil was similar to that produced by thyroidectomy in the same period but was probably of lesser degree. From three to thirty months after the beginning of treatment there was no appreciable difference in the condition of the patients treated with thiouracil and those treated with subtotal thyroidectomy. Continued use of thiouracil drugs appears to be a good alternative treatment of toxic goiter. Thyroidectomy is advisable when tracheal obstruction is present, when a drug reaction occurs and when the patient is unable or unwilling to attend regularly for an indefinite period. After the administration of thiouracil is stopped, relapses occur. The longer patients were followed after the cessation of treatment, the more frequently did relapse occur. It is impossible as yet to say whether such remission can be permanent.

Penicillin Prophylaxis in Acute Rheumatism.—Burke used penicillin by mouth as a prophylactic against attacks of pharyngitis, particularly those due to streptococcic infections, in an effort to prevent the recurrence of acute rheumatic manifestations in susceptible patients. Twenty patients who had had acute rheumatism within the previous twelve months were divided into two groups of 10. The patients in the treated group were given three pastilles, each containing 500 Oxford units of calcium penicillin, to suck each day. They were instructed to place the pastilles between the cheek and the lower gum, to allow them to dissolve slowly, and to swallow the saliva containing the penicillin in solution. After the prophylactic treatment had been continued for a year it was evident that rheumatic manifestations were five times and throat infections six times more frequent in the control group than in the treated group.

Note on Selection of Medical Students. E. S. Meyers and D. H. Meyers.—p. 203.

Basophilic Stippling, Especially During Chrysotherapy.—Parr and Shipton studied 20 patients taken at random from a series undergoing chrysotherapy. Basophilic stippling in the blood was revealed in all irrespective of the age or sex of the patient or of the variety of arthritis. The cases of rheumatoid arthritis investigated were divisible into two main types, those in which sweating and clammy cyanotic hands were present and those in which the skin was dry and normal and no sweating or cyanosis was present. Many of the patients who had a dry skin and only slightly raised blood sedimentation rate proved to be ideal for chrysotherapy with regard to both the clinical response to treatment and the absence of toxicity. The authors suggest that patients showing severe anemia, eosinophilia, increased blood sedimentation rate, a shift of the neutrophil cells to the left and cold, clammy, cyanosed hands or dehydration should be carefully checked from time to time for stippled cells in their blood to prevent the onset of deleterious reactions.

Nosologic Considerations on Pain in Disturbances of Liver and of Biliary Tract. L. Cornil, H. Walther and G. F. Bonnet.—p. 54.

Myeloma Following Bone Trauma and Osteomyelitis.—Loeper and his co-workers report the occurrence of myeloma in a woman and in 2 men aged 52 and 30. The woman had sustained a fracture of the arm five years before sternal puncture revealed cells of definite plasmocytic type, and examination of the urine demonstrated the Bence Jones body and x-ray examination revealed multiple cavities of the humerus, the femur and the tibia. The older man sustained a fracture of the femur five years before plasmocytosis was revealed on sternal puncture. Urinalysis revealed Bence Jones albumosuria, but x-ray examination was negative. In the younger man the myeloma resulted from an osteomyelitis of twenty-five years' duration, with a residual fistula through which the bone tumor became exteriorized. In these 3 cases, in contrast to Bloodgood's observations, the trauma or the infection did not reveal a primary disease of the bone. The trauma and the chronic infection were instrumental in producing the myeloma, supporting Coley's observations and Kjurkoff's concept.

2-Thiouracil in Heart Failure and in Angina Pectoris. A. Sanabria. —p. 143.

Cardiac Disturbances in Infectious Hepatitis.—Adler and Lyon report 8 cases in which infectious hepatitis and jaundice was accompanied with electrocardiographic and subjective signs of myocardial lesions. The author directs particular attention to prolongation of the QT time and elevation of the T wave.

High Oxygen Concentration in Cardiac Pain and Pulmonary Edema.—Lindgren studied the effects of 100 per cent oxygen under normal and increasing respiratory pressure in patients with cardiac pain and in pulmonary edema. Pain in angina pectoris and in myocardial infarction was relieved by 100 per cent oxygen, and the electrocardiogram improved in angina pectoris. Electrocardiograms with the typical signs of coronary insufficiency during rest showed improvement during such oxygen administration. One hundred per cent oxygen at an increased pressure of about 10 mm. of mercury has been used with good results in cardiac failure with acute pulmonary edema. The treatment has been life saving in eclampsia complicated with pulmonary edema. In pulmonary edema the increased pressure is of value by increasing the oxygen content of the blood and by diminishing the venous return.

Case of Celiac Disease in Uniovular Twins. S. Lahdensuu and O. Somersalo.—p. 2819.

Propylthiouracil in Treatment of Hyperthyroidism.—Kjerulf-Jensen and Meulengracht's preliminary evaluation of propylthiouracil compared with methylthiouracil is based on the results of treatment of 32 patients with hyperthyroidism. They increased the original dosage to 0.1 Gm. three times daily, or 40 per cent of their usual methylthiouracil dosage. Even the most resistant case reacted to the treatment, but in 2 instances the thyrotoxic sympoms failed to decrease notably in spite of a month's treatment; further treatment of these patients with methylthiouracil gave good results. There was no indication that propylthiouracil possesses any fundamental effect different from the known effect of methylthiouracil. Partly because of the smaller amounts used, there were fewer by-effects after propylthiouracil than after methylthiouracil. Typical drug fever was seen in only 1 patient, who was also sensitive to methylthiouracil.

Svenska Läkaresällskapets Förhandlingar

Some Proposals for Reforming Medical Training. H. Malmros.—p. 2877.

Pathophysiology and Therapy of Adynamic Ileus.—Edlund says that circulatory changes in the intestinal blood vessels due to reflex responses to stimulation of the peritoneum are most important in the pathogenesis of adynamic ileus. They cause decreased intestinal motility, disturbed resorption of the stomach and intestinal contents, changes in the composition of the blood with release of water, electrolytes and plasma albumin from the blood through the capillaries, and, as a result of the diminished blood volume, a state of shock. In the first phase of treatment circulatory disturbances are counteracted by supplying plasma, by mechanical drainage of the gastrointestinal canal and by oxygen inhalation. In addition, salt and glucose are given parenterally to counteract dehydration and chloropenia. In the second phase of treatment amino acids and glucose are administered to prevent inanition and proteinemia; later a diet rich in calories and especially in proteins. Careful preoperative treatment and choice of anesthesia, together with adequate postoperative treatment, are important in preventing postoperative adynamic ileus. Toxemia is an added factor in adynamic ileus of peritonitis. Intensified administration of carbohydrates and protein is indicated to increase the patient's general resistance and the resistance of the liver and to accelerate detoxification. Further, therapy with sulfonamide preparations and penicillin may be considered.

Book Notices

Western Reserve University Centennial History of the School of Medicine. By Frederick Clayton Waite. Cloth. Price, $6. Pp. 588, with illustrations. Western Reserve University Press, 2073 Adelbert Road, Cleveland 6, 1946.

This history of a medical school is not simply a parochial account of local events of interest only to the old grads but is also stimulating to the general medical reader. The volume is much more than the history of a medical school, as might well be anticipated from the scholarly pen of Frederick Clayton Waite, who occupies an esteemed position as a medical historian. The hundred years of this medical school, since its origin in 1843, is pictured in the setting of medical education in the country at large. Western Reserve shared the vicissitudes and irregular progress of other medical schools. An example of historian Waite's eagerness to relate his school to significant and often previously unrecorded events in the history of medical education is seen in the opening sentence of his chapter on homeopathy: "This chapter is inserted in a volume otherwise concerned with regular medical colleges because no printed account exists that covers the entire period of homeopathic medical education in Cleveland." The author is rightfully proud of the history of Western Reserve University School of Medicine, quoting Flexner as saying to the university president, after the famous survey, "The Medical Department of Western Reserve University is, next to Johns Hopkins University, which for various reasons occupies an exceptional position, the best in the country." Yet the pride of local accomplishment emerges from the book as merely a part of the author's appreciation of advances in medical education everywhere. The broadness of his approach will appeal to any one interested in the history of medical education.

Urgent Surgery. Volume I. Edited by Julius L. Spivack, M.D., LL.D., Associated Professor of Surgery, University of Illinois College of Medicine, Chicago. Cloth. Price, $10.50. Pp. 714, with 572 illustrations. Charles C Thomas, 301-327 East Lawrence Ave., Springfield, Illinois, 1946.

This is a comprehesive book covering a large field in surgery. Urgent surgery is defined as that type of surgery which is not traumatic or elective but comprises cases in which operation becomes imperative within a matter of days. The first four chapters cover blood transfusion, anesthesia, all types of intravenous infusions, shock, hemorrhage, septicemia and gas gangrene. These subjects are presented as one would deal with them in urgent surgery as defined by the author. The chapter on laparotomy is one of the best. It explains what is meant by laparotomy and stresses the important fact that if such a procedure is undertaken the operating surgeon must be equipped and qualified to deal with major pathologic conditions. It also covers the various types of incisions and their closure and takes up the question of drainage. Three chapters are then devoted to surgery of the stomach and duodenum, including gastrotomy and pyloric stenosis. The subject is handled in routine fashion, similar to most textbooks on surgery. In dealing with gastrotomy the Spivak tubovalvular gastrotomy is stressed, explained and illustrated in full detail.

The chapter dealing with the pancreas is well written and covers the field in a concise and clear manner. Carcinoma of the pancreas and adenomas of the pancreas are mentioned. As these lesions do not come under the category of urgent surgery the treatment is merely mentioned without going into detail.

A very full, long chapter is allotted to urgent surgery of the liver and bile ducts, covering the field thoroughly. The author strongly recommends the costal incision for most biliary surgery. Several controversial subjects are brought up. One is that the author prefers operating on the gallbladder before opening the common duct. His reasons are that he gets better exposure of the common duct and a wider operative field and that he removes a potentially infected organ before operating on the common duct. He stresses the importance of electrocoagulation of the gallbladder wall adjacent to the liver. He terms this "mucoclasia." In this chapter he briefly mentions thrombosis of the veins of the lower extremities as a possible complication and advises the rather unusual treatment of elevating the legs on a splint and using ichthammol ointment dressings.

The field of appendicitis is covered completely. Two controversial subjects are handled: how to manage the appendical stump (he advises the true inversion without suturing) and drainage. He advocates the use of drainage routinely in appendical abscesses and in those cases in which satisfactory peritonization cannot be accomplished.

The chapter on intestinal obstruction covers the field thoroughly. When resections are indicated the closed type of anastomosis is favored. The last few chapters deal with urgent surgery in infants and surgery of the colon. The last two chapters cover perforated peritonitis and nonperforated peritonitis. From the author's remarks in several places in the book, especially in the chapters on laparotomy and appendicitis, he seems to favor early ambulation of operative cases.

The illustrations are plentiful and well done. They are used mainly to illustrate various surgical technics.

The book covers the field of urgent surgery in a detailed and competent manner, including preoperative diagnosis and preparation; also the surgical technic involved in the various operations. It follows through with postoperative care. This book is ideally suited to the use of residents in surgery. It is too far advanced for medical students. For the experienced operator it will be of interest, but it does not cover any one subject profoundly enough to be used as a book of reference.

Daniel Coit Gilman, Creator of the American Type of University. By Abraham Flexner. Cloth. Price, $2. Pp. 173, with 3 illustrations. Harcourt, Brace and Company, 383 Madison Ave., New York 17, 1946.

The life and the scholarly and academic ideals and accomplishments of Daniel Coit Gilman, first president of Johns Hopkins University, are described in this stimulating volume. When Gilman accepted this post in 1875 there was no true university in his sense, or in the European sense, in this country. Gilman's ideal was the establishment of an institution in which scholars "should be free to pursue their own researches, stimulating their students to prosecute study with a truly scientific spirit and aim." Gilman was not interested in just another undergraduate college whose professors would be burdened with "doing the duty of schoolmasters." His ideas were immediately accepted by the board of trustees and were financed with the (then) munificent endowment of $3,500,000, most of which was in Baltimore and Ohio stock, which some years later became worthless. The spirit of Gilman carried this idea into full fruition in the quarter century of his sojourn at Hopkins and set a pattern for graduate education in this country, emulated since in our better universities and research institutes. Gilman's emphasis was on the securing of promising men and providing them with opportunities for research productivity. Nowhere in the university was this principle more effectively applied than in the medical school, where Gilman added such scholarly names as Welch, Osler, Halsted, Kelly, Mall, Howell and Abel. His achievement in the medical school was especially notable, since medical education in America at that time was a sorry spectacle. The story is well told by one who was first inspired by Gilman's ideals and who himself became a master. It will interest every one concerned with higher education and medical education.

The Anatomy of the Bronchial Tree with Special Reference to the Surgery of Lung Abscess. By R. C. Brock, M.S., F.R.C.S., Surgeon to Guy's Hospital, London. Fabrikoid. Price, $12. Pp. 96, with 142 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1946.

The anatomy of the bronchial tree has received attention by various authors. But this volume describes the unique anatomy of the bronchial tree. The author has made dissections of all the bronchi and has made metal casts of them. In addition he has made detailed bronchographic studies in the living subject to verify the interpretations which he presents in this volume. The illustrations are beautifully executed from the standpoint of photography and of artistic value. Many colored plates clarify the description in the text. The cost of producing these numerous plates, drawings and x-ray films must have been considerable. The Clinical Research Committee of Guy's Hospital gave a generous grant to the author in order for him to be able to present this beautiful work.

While the subject of the book is the anatomy of the bronchial tree, the purpose of the author appears to be the relationship to the causes of abscess of the lung and the methods of exact localization. With this in mind the work demonstrates most beautifully the anatomy of the bronchi. In addition to the approach to the localization there are numerous drawings from bronchoscopic appearances of the various larger bronchi. It is interesting to note that in the description of the lymph nodes at the hilus of the lung the author uses the term "lymph glands." This term is obsolete in this country.

The photographs of the x-ray films are in the positive. In the American literature one almost always finds the reverse, the negative film being demonstrated. It is interesting to note that the author rarely uses stereoroentgenograms but prefers to use many positions and particularly the lateral view together with the anteroposterior position. The author is convinced that abscesses of the lung are produced by direct aspiration into the various bronchi and states that the upper lobes of the lung are involved almost as frequently as the lower, depending on the position in which the patient may be lying following operations.

With regard to embolism as a cause of abscesses, the author states that "this misconception is held by many people, and the object of this chapter is to show that the causal factors responsible for the development of an abscess in any particular site in the lungs are chiefly inhalation and posture, and that far from disproving the hypothesis of bronchial embolism the frequent occurrence of abscess in the upper lobes is the greatest single piece of evidence in favor of bronchial embolism and against vascular embolism."

The author quotes the Rabin method of localizing abscesses frequently and much of the presented material shows the value of the injection of iodized oil and methylene blue at the area where the abscess is outlined previous to operation. The pagination is unique, the pages of the reading matter being numbered independently of the illustrations. This book is recommended highly to all physicians who are interested in diseases of the lungs, particularly thoracic surgeons. physicians and roentgenologists.

The Eye Manifestations of Internal Diseases. By I. S. Tassman, M.D., Associate Professor of Ophthalmology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Second edition. Cloth. Price, $10. Pp. 614, with 243 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1946.

This edition is somewhat enlarged by additions of material on epidemic keratoconjunctivitis, toxoplasmic encephalomyelitis and other subjects. The author states in the preface that he has added descriptions of ocular allergy. He has included only tuberculous uveitis, conjunctivitis and keratitis but does not mention others which are more important in "bridging any existing gap between the eye manifestation and other aspects of internal disease." There are numerous omissions which should be included in such a work. Under metastatic gonorrheal infection there is no mention of dacroadenitis. In the section on macular degeneration, more lengthy discussion should be made of heredomacular disease, senile macular degeneration, familial macular degeneration, Noguchi's disease, central angiospastic retinitis and other conditions. A full discussion of the relation of the eye to headaches and dizziness should have an important place in such a book. On page 167 under treatment of cataract the author states that regular examination should be more frequent as the cataract approaches maturity. The stage where close observation is necessary is during the much earlier intumescent stage when there is danger of glaucoma. On page 165 is the statement that "complicated cataracts are also considered as secondary cataracts." Secondary cataract is a term which should be used only for the membrane, capsule and organized cortex remaining after an extracapsular lens extraction or injury to the lens. On page 194 about angioid streaks it is stated that it is associated with diabetes, Paget's disease and inflammations of the choroid. No mention is made of pseudoxanthoma elasticum, which is much more commonly seen with angioid streaks than all the others combined. The book will have a wide popularity because, for the time being, there is no better one on the market.

Science and Scientists in the Netherlands Indies. Edited by Pieter Honig, Ph.D., and Frans Verdoorn, Ph.D. Natuurwetenschappelijk tijdschrift voor Nederlandsch Indië, Volume 102—Special Supplement. Cloth. Price, $4; £1.1.0. Pp. 491, with 134 illustrations. Board for the Netherlands Indies, Surinam and Curaçao, 10 Rockefeller Plaza, New York 20, 1945.

According to the editors this volume is intended to present a picture of the development and status of various branches of the natural sciences, pure and applied, in the Netherlands Indies. They call attention to the fact that the book was prepared during the military occupation of both the Indies and the Netherlands, which made it impossible to obtain the collaboration necessary for a complete history of science in the Netherlands Indies. The book is made up of original articles and reprints of previous publications dealing with the development or status of various branches of science in the Netherlands Indies and also of travel accounts, biographic sketches, reviews and a list of scientific institutions, societies and workers at the time of the Japanese invasion. The editors are to be congratulated, for they have produced a valuable book which should fulfil their hope that this volume might be of use and interest to visiting civilians and members of the armed forces of North America, Great Britain and other countries. Moreover, it affords a valuable reference work which should be useful to scientists working in many fields throughout the world, especially to those who are concerned with the future progress of international health and human welfare.

Squint and Convergence: A Study in Di-Ophthalmology. By N. A. Stutterheim, M.D. Cloth. Price, 15s. Pp. 95, with 41 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W. C. 1, 1946.

This small volume is a culmination of work done and articles printed in the literature over a period of the last twenty-five years. The trend of the author's thoughts and somewhat radical ideas were presented in a previous volume entitled "Indications for the Kinetic Treatment of the Eyes." The basic idea of this new physiologic approach to the correction of convergent strabismus is that fusion is a function of the nervous system integration and therefore is wholly independent of any refractive error. A battery of prisms is passed before each eye in increasing strength until the patient's abduction or divergence insufficiency is overcome. The refractive error remains uncorrected. The last half of the volume is completed with case reports and results. Stutterheim's colleagues have shown little desire to follow his work, either to corroborate it or to find fault. Until others have taken the time and effort to verify his findings, the work must be looked on as a most interesting experiment.

The Thyroid Gland in Medical History. *By Alfred H. Iason*, M.D., Instructor of Anatomy, New York Medical College, New York, Fabrikoid. Price, $3. Pp. 136, with 50 illustrations. Froben Press, 4 St. Luke's Place, New York 14, 1946.

Iason has compiled a book that will be found useful to the specialist in thyroid physiology or pathology, for it apparently provides all the basic information about the development of our knowledge of the thyroid gland from the Egyptians to our day. The book is well illustrated, the paper is excellent and the format such that it can be read with comfort. The author has put his material together in a most orderly fashion, but in so doing the book, from the point of view of the nonspecialist reader, loses background. Focusing wholly on the thyroid, one has the impression that other actors too must have been concerned in the play. But to trace them would have made a much bulkier book and might have diverted the reader from the subject of the dissertation. As it is, the volume is a worth while contribution to our knowledge.

Studies of Compulsive Drinkers. Part I. Case Histories. By Herman Wortis, M.D., and Leonard R. Sillman, M.D. **Part II. Psychological Test Results.** By Florence Halpern, M.A. *Edited by* Jane F. Cushman, M.A., and Carney Landis, Ph.D. Foreword by Nolan D. C. Lewis, M.D. [Distributed by Quarterly Journal of Studies on Alcohol.] Paper. Price, $1. Pp. 90. *Hillhouse Press*, 432 *Temple St., New Haven*, Connecticut, 1946.

As usual, Florence Halpern's psychologic work and contribution are valuable in this monograph, containing in part I 18 detailed and interestingly presented case histories with clinical and test findings and in part II psychologic test results.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HISTIDINE TREATMENT OF VASCULAR DISEASE

To the Editor:—The treatment of vascular disease by the use of histidine and ascorbic acid was discussed in a recent article in The Journal (Wirtschafter and Widmann, March 1, 1947). The article did not describe the routine to be followed or the dose. Information on this subject would be appreciated.

Henry B. Gotten, M.D., Memphis, Tenn.

ANSWER.—The two compounds are administered in the following manner: All patients are started with an intravenous injection of 500 mg. of sodium ascorbate. This injection is a preliminary one and is not repeated thereafter. It is meant purely as an attempt to saturate the patient with ascorbic acid prior to the institution of the actual therapy. Immediately after the intravenous injection the patients are put on a regimen consisting of the intramuscular injection of 5 cc. of a 4 per cent aqueous solution of l(—) histidine monohydrochloride and the subcutaneous injection of 100 mg. of sodium ascorbate. These injections must be given separately. The gluteal muscle for the injection of the histidine compound and the area of the deltoid for the injection of the sodium salt of ascorbic acid are preferred. The reason for giving these injections separately is to prevent the reaction from proceeding at too rapid a rate. Though in the original article the time intervals between the administration of the two compounds varied from every four to every twelve hours, it is now believed that it is best to give the drugs every four hours day and night. If this is not possible, the drugs should be given not less often than every six hours day and night. Any longer time intervals will only prolong the time of healing and sometimes triple the patient-hospital days. Along with the injections, all patients receive 200 mg. of ascorbic acid by mouth, three times daily, a total of 600 mg. orally. When open lesions exist, either wet dressings in the form of boric acid or packs of isotonic solution of sodium chloride are used continuously or the wound is dressed with petrolatum gauze daily. Depending on the nature and severity of the wound, wet dressings may have to be repeated two to four times during a twenty-four hour period. The sodium salt of ascorbic acid must be used. The methyl glucamine salt of ascorbic acid and the sodium bisulfite salt of ascorbic acid have been tried and both of these have been found to produce a definitely lessened reaction. This has been confirmed by the patients themselves. The solutions used must be clear. Ascorbic acid solution which is definitely yellow is not as active as the clear solution. Similarly, it must be emphasized that the histidine solution should be clear and not a light brown, nor should it contain a brownish precipitate.

DANGERS OF PINWORM FISH FOOD

To the Editor:—Pinworms are commonly cultured as food for tropical fish. Is this type of pinworm capable of infesting man? Is the use of this pinworm for fish food hazardous?

M.D., Michigan.

ANSWER.—Dealers advise that the "pinworms" cultured as food for tropical fish belong to the genus Tubifex and related genera. These worms are free living annelids and are not related to the pinworm which infects man. This worm, Enterobius vermicularis, is a strictly parasitic form and has been reported only from man and the higher apes. Effort has been made to infect experimentally several other animals without success. Under the circumstances there is no hazard in the use of the free living annelids mentioned as fish food.

POSTOPERATIVE IRRADIATION OF CHOROIDAL MELANOMA

To the Editor:—What is the present status of postoperative irradiation by radium or x-rays of melanoma of the choroid?

M.D., Pennsylvania.

ANSWER.—Good evidence that postoperative irradiation is of value in the treatment of melanoma of the choroid does not exist. However, its use must be considered with the view that it may possibly be effective.

HONEY FOR TREATMENT OF PEPTIC ULCER

To the Editor:—A man with a peptic ulcer has been under rigid management for many years, with only fair success. Seven months ago he began taking honey as a therapeutic measure. He is now on a normal diet and has not had symptoms since starting honey. Two friends of his have also started this diet of honey and whatever else they want to eat. They report that they are also symptom free. What is the therapeutic rationale of using honey in the treatment and management of peptic ulcer?

M.D., Wisconsin.

ANSWER.—The natural course of chronic benign peptic ulcer is characterized by periodicity of symptoms for reasons not clearly understood. This together with the important although intangible effect of mental suggestion renders the evaluation of any treatment difficult. (Palmer, W. L., in Portis, S. A.: Diseases of the Digestive System, ed. 2, Philadelphia, Lea & Febiger, 1944, p. 219). The patient and his 2 friends are convinced, no doubt, that honey is an "ulcer cure." The possibility that all 3 had spontaneous remissions would seem an unsatisfactory explanation. On the other hand, honey has a variable composition. The chief constituents, dextrose and levulose, do not have any specific therapeutic effect in peptic ulcer. To attribute the relief of ulcer symptoms to the use of honey per se would also seem an inadequate explanation. In this connection it is interesting to note that of a group of 20 ulcer patients treated with daily injections of 5 cc. of distilled water 12, or 60 per cent, became symptom free. Five, or 25 per cent, became symptom free after the first injection (Sandweiss, D. J.: Treatment of Gastroduodenal Ulcer with Histidine Monohydrochloride, THE JOURNAL, April 25, 1936, p. 1452). Such observations emphasize the difficulties in evaluating ulcer treatment. They also illustrate the importance of mental suggestion, enthusiasm, faith or whatever term one wishes to apply to the frequently observed phenomenon of "ulcer cures" following nonspecific therapy. The importance of these intangible factors in the treatment of peptic ulcer is well recognized even if not clearly understood. Consequently the therapeutic rationale of the use of honey seems quite clear. One can hardly escape the conclusion that it is only of psychotherapeutic value.

DERMATITIS IN MEAT HANDLER

To the Editor:—A woman worker in a lunch-packing factory develops a severe acute contact dermatitis involving the face and neck and arms (all exposed areas of the body) whenever she works at her usual job making hamburger "patties" from meat (which is "untreated" at the plant). The hands, including the dorsal surfaces, are entirely clear during the handling of the meat. Roach powders and fly sprays, which are used from time to time at the factory, have been eliminated as a cause. That the dermatitis is caused by something at work is proved by the fact that it disappears after two weeks at home and treatment with the usual wet compresses and recurs one hour after she returns to her job. A warm air blower which is the only spray in the plant is used to blow out the grinding machine. (No chemicals are used.) The patient does not have an allergic history and has eaten meats of all kinds all her life. Ordinary lighting facilities are used in the plant.

M.D., Ohio.

ANSWER.—There can be but little doubt that the patient described in the query has an occupational dermatitis, as shown by the fact that she gets well when she is away from work and the eruption returns when she goes back to work. In order to find the actual irritant in her occupational environment which causes the eruption it would be necessary to make an exhaustive study of the substances with which she comes in contact. "Patties" are not entirely excluded in spite of the fact that she has eaten meats of all kinds, because hamburger patties may contain spice and other substances which she does not ordinarily eat. Besides, it is possible to develop a dermatitis from contact with raw meat and yet not develop dermatitis when the same meat is cooked and eaten.

The warm air blower also should be investigated, because instances have occurred wherein warm air brought from one part of the plant has carried an irritant to another part of the plant. Cases have also occurred wherein warm air flowing in the direction of a cold area has been known to pick up irritants on the way, which have caused dermatitis on workers in the area of final distribution of the warm air. A series of patch tests as a result of such an investigation may reveal the actual irritant.

As preventive measures while working, it is suggested that impervious sleeves made of a plastic such as vinylite be worn on the arms, and that the face and neck be covered by a protective ointment such as equal parts of lanolin and cold cream and that before the lunch hour the ointments be washed off and reapplied immediately after lunch.

DIAGNOSTIC PROBLEM—POSSIBLE EPILEPSY

To the Editor:—A man aged 24, about 5 feet 6 inches (168 cm.) tall, weighing 175 pounds (79 Kg.), was involved recently in an airplane crackup. He was taken from the plane in shock, which was of eight hours' duration. He was given intravenous saline solution for three days and epinephrine and morphine injections. His previous history included nervousness, contusions and lumbar strain. The blood pressure is 100/68. Since this accident, whenever the patient is under tension and becomes nervous he begins shaking and "blacks out." He becomes cold to such a degree that his teeth chatter and he attempts to pull himself together in an effort to get warm. He has severe headaches and vomits. His knees give way under him. His entire body becomes red and even his eyes are bloodshot. It is my impression that the blood vessels become dilated. It seems as if one big hive was manifesting itself. If he tightens his face, clenches his fist and tautens his muscles or skin, the area becomes white. The patient appears to be in extreme shock during this period. In recovery there are pains in the knees and pins and needles sensations in the fingers. At cessation of the spells he feels well enough to participate in any form of work or play. Three of these spells occurred during the last week—one at a football game, one at the table and the third while making a hard shot at pool. Is this a petit mal epilepsy?

Morris H. Pett, M.D., Gloucester, Mass.

Answer.—Before a satisfactory diagnosis can be made further studies should be carried out including the blood pressure and blood sugar during and following an attack, x-ray examination of the skull, examination of the cerebrospinal fluid including that of the pressure, cells, protein, Wassermann and colloidal gold, and a complete physical and neurologic examination. It may also be desirable to perform a ventriculogram or an encephalogram.

The possibility of a "diencephalic epilepsy" such as was described by Wilder Penfield (*Arch. Neurol. & Psychiat.* **22:** 358 [Aug.] 1929) must be considered. Such attacks might arise from a tumor in the third ventricle. Such a lesion would also account for the associated severe headaches and vomiting—a paroxysmal hypertension from an adrenal tumor seems unlikely unless the phase of vasodilatation is secondary and is preceded by one of vasoconstriction. In many respects the attacks suggest the response to an intravenous injection of histamine, and this may be an unusual histamine reaction. The reason for such a condition is of course not obvious.

STABILITY OF MORPHINE AND ATROPINE SOLUTIONS

To the Editor:—How long will ampules of morphine sulfate or morphine sulfate and atropine preserved in chlorobutanol and sodium sulfite keep? Is it safe to use them at all after several years? How soon will their potency diminish?

Anthony M. Susinno, M.D., Palisades Park, N. J.

Answer.—Solutions of morphine sulfate are fairly stable and would probably keep indefinitely in ampules or if protected by chlorobutanol and sodium sulfite against bacterial or fungous contamination. A 1 per cent solution of morphine hydrochloride is official in the British Pharmacopeia. It contains 25 per cent of alcohol. Atropine sulfate solutions deteriorate quite rapidly. Sollmann's Manual of Pharmacology, sixth edition, page 376, quotes Simon, 1915, that there is considerable loss of activity even in three days, and Joachimglu, 1915, that sterilized solutions in ampules retain their full activity for at least four weeks. The rate of change varies with conditions which are not always predictable. The change involves only the potency; the toxicity would not be increased. It would be quite safe to use the ampules after several years, but they may not be fully active.

ELECTROCOAGULATION FOR POSTTONSILLECTOMY HEMORRHAGE

To the Editor:—Is electrocoagulation a satisfactory means for hemostasis after tonsillectomy? Is secondary hemorrhage more likely after electrocoagulation than after spontaneous clotting, sponge compression, hemostat crushing or tying? Can the concentration of ether vapor in the patient's alveolar air be such as to make the use of electrocoagulation in the mouth hazardous if, after the induction of deep surgical ether anesthesia, all anesthesia equipment is removed from the operating room?

M.D., Texas.

Answer.—Electrocoagulation can be used to stop bleeding after tonsillectomy. It is not as satisfactory as sponge pressure, the hemostat or the ligature. The latter are simple, are easy to use and do not require special precautions as to anesthesia.

The methods used to obtain hemostasis vary with the experience and inclination of the operator. In general, one should attempt to obtain a dry tonsillar fossa, using methods that give minimum tissue injury and the shortest amount of time for anesthesia. Sponge pressure harms the tissues the least but is more time consuming and less sure. The hemostat is more accurate because it can be applied directly to the offending spot but, because of its crushing effect, there must be a certain amount of secondary tissue necrosis and sloughing and danger of bleeding later. The ligature that is tied over the end of a hemostat may come off; the ligature that is placed with a needle requires skill; the needle may break, and there is danger of introducing infection into the deep tissues of the neck.

All three methods may be employed, from the simple to the more difficult, as conditions demand. At all times as little trauma as possible is inflicted and, if ether is used, the time of anesthesia is made as short as possible.

If electrocoagulation is used for hemostasis, the least amount of current necessary is applied, so that tissue destruction is kept to a minimum. It can be a useful instrument in practice, although there are limitations. The apparatus often requires adjustment, and this means that one other person must be present besides the operator. In an adult, or when a local anesthetic has been used, there may be little difficulty in gaining access to the desired area. However, a child with a metal mouth gag in a small mouth offers difficulties in approach and opportunities for short-circuiting and burning of the lips and gums. Before using electrocoagulation one should try simpler and less dangerous methods.

Secondary bleeding follows electrocoagulation more often than after the use of other methods; and, in addition, this bleeding is apt to be more stubborn.

The hazard of explosion is definitely present if electrocoagulation is attempted in the course of an ether anesthetic unless the patient is allowed to waken to such an extent that the ether concentration in the lungs is minimal. At this stage the patient is not anesthetized to a worth while degree, from a pain killing point of view. Also at this stage he is apt to retch, vomit and be so active and uncooperative as to make a painstaking procedure difficult, if not impossible.

BRIDGING OF THE SELLA TURCICA

To the Editor:—A man has had chronic headaches for years. Roentgenograms reveal calcification of the sella turcica or rather a bridging over of the sella. What is the significance of this finding and can it be the cause of his headaches? What is the treatment?

Arthur Henrichsen, M.D., Van Nuys, Calif.

Answer.—Bridging of the sella due to close approximation of the interior and posterior clinoid processes is found normally and usually is not significant. However calcification in, above, below or to the side of the sella turcica is very significant. It is found in (1) a calcified internal carotid artery, (2) suprasellar cysts, (3) intrasellar tumors such as adenoma or glioma, (4) meningioma and (5) glioma of the optic chiasm. The patient described in the query should have repeated testing of his visual fields, i. e. every 15 degrees, for form and color. Both optic nerve heads should be examined for optic atrophy or papilledema. Glucose and insulin tolerance tests also should be made. If all these tests are within normal limits then other causes should be sought, such as hypertension or arteriosclerosis.

VISION TESTS

To the Editor:—What are the advantages of the Telebinocular (Keystone Company) or the Massachusetts vision test (Welch Allyn Company) over the Snellen Chart for testing school children?

D. H. Lawler, M.D., Hammond, Ind.

Answer.—In the visual examination of school children the advantages of the Telebinocular, which is basically a stereoscope, are that (1) little space is required for use, (2) it combines reasonably accurate tests for distance visual acuity, muscle balance, color vision and stereopsis and (3) it facilitates rapidity of examination, especially in groups of 15 or more, and in older children and adults. Among its disadvantages are (1) expense, (2) limited adaptability for small groups and (3) possibility of misinterpretation of the information afforded.

The advantages of the Massachusetts vision test are that (1) it is designed especially for the examination of school children and is well adapted for those in the primary grades, (2) it combines an accurate test for visual acuity and muscle balance both for distance and near and affords a possible separation of hypermetropes from myopes and (3) it facilitates rapidity of examination especially with large groups. Among its disadvantages are its cost and the advisability of having trained help in its use.

The Snellen Chart has the advantages of being easily procurable, inexpensive and easy to install. Small groups may be practically tested for distance visual acuity with literate or illiterate Snellen Charts if intelligently used. Among its disadvantages are that (1) variations of illumination are often associated with its use, (2) its letters and figures are easily memorized and (3) its usefulness is limited to distance visual acuity.

TREATMENT OF CORONARY ARTERY DISEASE

Dicumarol Therapy

O. P. J. FALK, M.D.
Assistant Professor of Clinical Medicine, St. Louis University School of Medicine
St. Louis

Though the long range outlook in any phase of the treatment of coronary artery disease is necessarily colored by the inherent progressive trend of an essentially degenerative process, with all of its unpredictable proclivities, nevertheless a favorable outcome could reasonably be anticipated in about 80 per cent of well managed myocardial infarctions following coronary occlusion. It now appears that with the newer developments in anticoagulant therapy, there may be justification for a revision of the philosophy of treatment by adopting the more positive program of management offered by Dicumarol (3,3′-methylene-bis-[4-hydroxycoumarin]) in addition to the established methods of control.

In the treatment of coronary artery disease in general, the following important considerations necessarily influence the symptoms and signs as well as the prognosis and therapeutic response: (1) the type of coronary syndrome presented, whether angina pectoris, acute coronary insufficiency or actual occlusion; (2) the presence and extent of any ensuing myocardial infarction; (3) the amount of associated cardiac damage and consequent impairment of myocardial reserve. This can often be inferred by the antecedent history of response to effort and stress *before* the acute coronary episode and is further indicated by electrocardiographic, roentgenologic and other laboratory studies, and (4) the constitutional background of the patient, including heredity and temperament, associated hypertension or metabolic disorders and the general vascular status.

ANGINA PECTORIS

This is an event that ofttimes casts its shadow before. Preliminary warning of impending angina pectoris may take the form of a vague, indefinite substernal or epigastric discomfort following effort or emotional stress, especially after a large meal. The overweight, the hypertensive and the diabetic persons seem particularly vulnerable, and anemia, paroxysmal tachycardia and hyperthyroidism may be contributing factors. Anginal subjects are more frequently than not possessed of a hyperreacting temperament; they are characteristically restless, often without natural or cultivated tranquillity and poise, and seem notably lacking in the ability to relax or let up on sustained tension in their occupational or even recreational pursuits. The implications for guidance appear obvious, but correction is usually difficult and failure of accomplishment notorious.

Effective management of the anginal state entails carefully planned reduction of cardiac demand in the face of impaired coronary supply, which offers far greater possibility of adjustment than do currently available measures for increasing coronary flow. The most effective measure at the physician's command is a positive ban on smoking, because of the dual cardiac handicap which tobacco presents; the vasoconstrictor action of nicotine and the increase in the level of carbon monoxide in the blood (tables 1 and 2).[1] Not only does this impair its oxygen-carrying power but the relative anoxia may readily touch off a susceptible coronary reflex just as disease of the gallbladder may initiate an irritable coronary constrictor mechanism. The combination of a sensible protective philosophy of living and the curtailment of smoking will control many an effort anginal syndrome.

Other therapeutic measures that appear to merit a place in the treatment of angina pectoris include the use of nicotinic acid, papaverine and alcohol in moderation and teaching the anginal subject to anticipate unavoidable circumstances, such as going out in cold air, by using $\frac{1}{200}$ to $\frac{1}{100}$ grain (0.3 to 0.6 mg.) glyceryl trinitrate sublingually in order to prevent anginal pain. No harm can accrue from frequent resort to this valuable measure. Alcohol is probably the best coronary dilator, with papaverine more adaptable to protracted action when needed. The conventional dosage of papaverine has undoubtedly been inadequate, as it appears to require from 2 to 4 grains (0.13 to 0.26 Gm.) three or four times a day to be most effective in preventing "angina decubitus" or in controlling a lowering effort threshold of anginal pain. The use of nicotinic acid because of its vasodilatory effect appears to be justified in an attempt to increase the collateral coronary supply.

In the matter of xanthine derivatives my observation parallels that of Evans and Hoyle,[2] Steinberg and Jensen,[3] and Stevens,[4] in that these compounds are generally ineffective in the management of effort angina uncomplicated by myocardial failure, although apparent clinical response appears to justify their use in those cases that do show improvement.

Read in a symposium on "Treatment" before the Section on Experimental Medicine and Therapeutics at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

As to the other forms of treatment in current use, I feel that iodides are probably of value but that androgen therapy does not appear justified. The beneficial effect of small doses of thyroid extract to 21 patients was recently reported by Lerman and White[4a] with the thought of producing general vasodilatation by increasing the metabolic rate. These investigators considered that this effect might decrease the work of the heart even though cardiac output per minute was increased. Thyroid also tends to lower cholesterol blood levels, an effect which in the present state of medical knowledge appears to be desirable. The dosage should be small (½ to 1 grain [0.03 to 0.06 Gm.] a day) and cholesterol levels should be checked.

The importance of mild sedation cannot be overlooked in the management of chronic coronary insufficiency with angina, but it must be remembered that in older subjects, particularly those with cerebral vascular changes, there may develop intolerance to protracted barbiturate therapy. When barbiturate drugs are employed they should be alternated with other sedatives such as bromides, carbromal or perhaps codeine.

In cases in which increasing frequency or severity of anginal seizures, with an ever lowering threshold of effort tolerance, perhaps to the point of "angina decubitus," suggests the danger of approaching occlusion, the most effective coronary vasodilator available is an adequate dosage of papaverine by mouth or even intravenously, should the need appear urgent in order to ward off threatened occlusion or at least to limit regional vasoconstriction if complete occlusion with ensuing infarction appears inevitable.

In the treatment of effort angina in the obese with protruding abdomens, I have noted considerable improvement in effort capacity from adequate abdominal support, such as that described by Kerr[5] in the form of the Kerr-Lagen belt. On fluoroscopic examination the diaphragms of such persons are often below the normal position, and their movement apparently is limited by the weight of the abdominal viscera. Partially restored diaphragmatic function by an elastic, lifting type of support apparently aids the return flow of blood to the heart. In my observation androgen therapy has not been effective in angina pectoris.

THE PREVENTION OF ACUTE CORONARY EPISODES

Given a case of typical effort angina in which such perpetuating influences as overweight, diabetes, hypertension, anemia, hyperthyroidism and faulty habits of living have been dealt with as effectively as possible, are there any specific measures which may further protect the heart against sudden catastrophe or at least minimize that possibility? Such a question naturally presents a therapeutic challenge. The problem is to make the most of what coronary supply is potentially available, therefore one seeks to discourage such vasospastic influences as tobacco, cold and emotional stress while protecting coronary reserve by the curtailment of unnecessary demands on the heart and guarding against the dangers of gastric overdistention and undue fatigue. All this entails thoughtful planning and understanding cooperation attainable only by cultivated self control and self discipline, characteristics which are all too infrequently encountered in the mental attributes of the typical anginal subject, to whom the application of the proverb, "He that ruleth his spirit is greater than he who taketh a city," seems particularly appropriate.

A painstaking review of the anginal subject's daily activities by the clinician is likely to prove far more useful and effective than any regimen of drug or biologic therapy now available. It is astonishing what obvious and commonplace circumstances, heedlessly encountered by the average anginal subject, may be avoided or at least moderated by the cultivation of a sensible, protective attitude of living, thus helping to bridge the gap between physiologic demand and attenuated coronary supply. Therapeutic measures aimed at stepping up coronary flow must necessarily be directed toward an attempt to enhance collateral circulation around a narrowed channel, a process necessarily long and uncertain even if eventually successful. In the meantime protective measures to conserve the lowered coronary reserve must be emphasized and insisted on in any thoughtful program of management. Only in as far as such a program is successful can one hope to delay eventual coronary occlusion or acute coronary insufficiency at least as long as the attendant physiologic and pathologic conditions permit.

It is known that the reduction of blood pressure after spinal anesthesia may precipitate acute occlusion in a coronary subject. Furthermore, coronary occlusions tend to occur at night when the tide of pressure is at low ebb. If this nocturnal lowering be in any way accentuated after a day of unusual effort and consequent fatigue, then fatigue might well constitute a precipitating influence in bringing about an occlusion during the ensuing night. Clinical observation seems to justify this concept and consequently appears to rationalize the importance of avoiding fatigue at any cost, in the interest of which a period of rest during the day is highly desirable if not imperative. Two grains (0.13 Gm.) of papaverine before retiring after a day of unusual strain or stress, particularly when accompanied by the least suggestion of substernal uneasiness, is indicated as a logical effort toward the maintenance of coronary relaxation. The administration of similar or larger doses through the day may be indicated, as papaverine is the best coronary vasodilator in contemporary usage. The longer acting nitrites, such as mannitol hexanitrate and erythrityl tetranitrate, three or four times a day, have occasionally been effective in preventing attacks, in cases in which anginal seizures respond well to glyceryl trinitrate but require a great many tablets daily. As stated previously, smoking should be interdicted, whereas the use of alcohol in moderation is permitted in cases in which it is well tolerated, since it apparently exerts a protective influence probably because of its vasodilatory effect.

IMPENDING OCCLUSION AND ACUTE CORONARY INSUFFICIENCY

The imminence of complete closure developing in an already narrowed coronary vessel is suggested when anginal pain results from ever lessening degrees of effort or stress or when it occurs during rest, with or without a history of preceding effort angina.

Acute coronary insufficiency may be brought about by a cardiac overload beyond the capacity of narrowed coronaries to deliver blood, or may result from impoverishment of the supply of blood after hemorrhage, shock or the dehydration of any severe debilitating illness in a coronary subject. Such coronary failure may result in irreversible myocardial changes due to prolonged anoxia, so that infarction often develops. This can at times be averted by the prompt intravenous injection of 1 to 2 grains (0.06 to 0.13 Gm.) of papaverine, followed by theophylline ethylenediamine intravenously where indicated and by prompt oxygen therapy when available. If papaverine is ineffective within a few minutes, the subcutaneous or even intravenous use of morphine is in order, should the distress be serious or prolonged. The intravenous administration of theophylline ethylenediamine often proves beneficial when congestive failure develops; otherwise it is best avoided, because it increases the work of the heart proportionately more than it enhances coronary flow. Meanwhile the possibility of a developing myocardial infarction must always be kept in mind so that appropriate management can be instituted where indicated.

CORONARY OCCLUSION WITH MYOCARDIAL INFARCTION

Presented with a clinical picture of coronary occlusion and developing infarction, the first consideration should be the relief of pain followed by treatment of shock and prevention of further extension of coronary thrombosis by decreasing the thrombosing tendency with Dicumarol. The established conventional measures, though apparently sound and thoughtful procedures, nevertheless are all directives that might tend to encourage further thrombosis, such as inactivation and heavy sedation, augmented by dehydration incidental to sweating, frequent nausea and vomiting and consequently restricted fluid intake. Such dehydrating measures, sometimes further enhanced by the effect of the xanthine derivatives, decrease the fluidity and the volume of the blood.

TREATMENT WITH DICUMAROL

Dicumarol therapy represents the first step in the form of a positive therapeutic approach to the problem of coronary thrombosis and ensuing myocardial infarction, except for oxygen. The eventual place of this drug in the management of coronary occlusion cannot be arbitrarily stated at this time, much further comparative investigation being essential before any final conclusions can be drawn. The American Heart Association is setting up a committee under the chairmanship of Dr. Irving S. Wright, composed of the heads of large medical services who will be asked to use Dicumarol in alternate cases in an attempt to evaluate its influence on mortality. Wright[9] has treated 80 patients, in whom the anticipated mortality appears to have been reduced at least a third by comparison with previous series on conventional therapy. Wright found that Dicumarol had not aggravated the disease in any patient, and there was no evidence of recent hemorrhages in the intima of the coronary vessels in autopsied hearts. In no case was there any evidence that the old thrombus might have resolved or that the progression of an established infarction had been intercepted. It is realized that such a process cannot be anticipated, but it is thought that the drug may combat the tendency for propagation of a thrombus and may reduce the tendency toward phlebothrombosis and intramural thrombi as well as the incidence of consequent pulmonary infarction and systemic embolism.

Peters, Guyther and Brambel[10] have reported a reduction of embolic phenomena to one-eighth and mortality rate to one-fifth in comparing 50 dicumarolized with 60 nondicumarolized patients, and they concluded that such reduction appeared sufficiently significant to warrant further clinical evaluation of anticoagulant therapy.

Nichol and Page[11] used the drug in 50 consecutive occlusive episodes, with a history of previous myocardial infarction in 20. All 26 patients who suffered their first attack survived. Eight others died within the first six weeks. Six necropsies were performed which failed to reveal any mural thrombi or systemic or pulmonary emboli on these dicumarolized patients.

Contraindications to Dicumarol therapy in coronary occlusion include hemorrhagic blood dyscrasias, advanced hepatic disease, a history of ulcer or recent hemorrhages of the gastrointestinal tract and renal insufficiency which might prevent proper excretion of the drug.

It should be borne in mind that dicumarol therapy may influence to some extent the sedimentation rate, thus making this useful guide concerning progress somewhat less consistent and dependable, although in my experience the test is still useful and worth observing.

ROUTINE FOR DICUMAROL THERAPY

1. Patients must be hospitalized and Dicumarol therapy must not be attempted unless it is certain that the laboratory is prepared to make accurate prothrombin readings, which must be done each morning before the day's dosage of the drug is given.

2. Preliminary management consists in the administration of papaverine intravenously, with oxygen and morphine if necessary.

3. After the diagnosis is established, check the prothrombin level and give 300 mg. of Dicumarol by mouth.

4. Repeat the dosage of 300 mg. daily after the morning prothrombin level is determined, until 50 per cent is reached.

5. After 50 per cent is reached, give 100 mg. of the drug each morning until 35 per cent is attained.

6. Now stop the medication for several days (as the level is likely to drop lower without further dosage). Thirty-five per cent is the stop signal!

7. When the level again rises above 35 per cent, give 50 to 100 mg. of the drug daily, attempting to hold the level between 35 per cent and 50 per cent.

8. Keep this level for four to six weeks, as long as the patient is in hospital.

9. If the level gets down to 15 per cent (rare), watch for hemorrhagic phenomena, such as red cells in urine, petechial spots or purpuric areas. Treatment: Give 60 to 72 mg. of synthetic vitamin K intravenously; give the second dose in four hours.

10. In the event of alarming hemorrhage, give *freshly* citrated blood as often as needed. Blood loses its prothrombin in from twenty-four to thirty-six hours.

Since 1942, Barker[12] has reported no serious or fatal hemorrhage except in 1 patient with carcinoma of the duodenum, in over 1,000 cases of all types treated with Dicumarol.

For the pain of an actual occlusion just as in threatened occlusion, intravenous papaverine should be given promptly, followed in ten to fifteen minutes by hypodermic or intravenous morphine if needed. Such measures not only relieve pain rapidly but appear to minimize shock and may even serve to limit the coronary vasoconstrictor reflex, with all the implications such limitation may have on the ultimate extent of the infarcted area. Prevention of reflex vagus vasoconstriction by the administration of 1/75 grain (0.86 mg.) of atropine appears to be a sound measure, even though no more than a well founded suspicion of developing infarction exists. The antifibrillation effect of papaverine, as demonstrated by Lindner and Katz[13] in experiments on dogs, appears to justify the clinical use of this drug in myocardial infarction. LeRoy and Snider[14] demonstrated that after coronary ligation in dogs there was a generalized coronary vasoconstriction subsequent to the myocardial infarction. This seemed to be the factor bringing about ventricular fibrillation, which, when it occurred, appeared to be the immediate cause of death in animals succumbing to the experiment. It would appear that the protection of the regional myocardium from vasoconstrictive reflexes, which might extend the area of infarction or even produce fatal ventricular fibrillation, constitutes sufficient rationale for the use of papaverine in all cases of severe or sustained coronary pain.

Absolute physical and mental rest is of course imperative. Anxiety should be attenuated in every way possible. Oxygen given by nasal catheter or comfortable facial mask is an important protective measure and is always indicated, particularly in severe infarctions.

The occurrence of frequent ventricular extrasystoles after myocardial infarction appears to be an ominous sign. Woods and Barnes[15] observed that the more frequently they occurred the greater was the mortality. It is the opinion of several observers that infarcted areas of myocardium are hyperirritable and constitute foci for ectopic beats, which by their summation may lead to ventricular fibrillation, a frequent cause of sudden death after myocardial infarction, and one which can apparently be minimized by the use of quinidine sulfate, which seems to be more effective as a prophylactic agent against ventricular tachycardia and fibrillation than as a curative one. I[16] have been using 3 grains (0.2 Gm.) of quinidine sulfate three times a day in the management of severe myocardial infarctions, particularly where there is a tendency to extrasystoles.

During the period of convalescence from myocardial infarctions, because of the lowered blood pressure and prolonged period of rest in bed, circumstances are favorable for the formation of thrombi in the iliac veins, from which source pulmonary embolisms produced 10 per cent of the deaths following acute myocardial infarction, as reported by Woods and Barnes[15] and Bean.[17] The latter reported that every instance of fatal massive pulmonary embolism after myocardial infarction had arisen from the veins of the pelvis or lower extremities. In addition to the anticoagulant effect of Dicumarol, one may combine knee flexing and deep breathing after the method of Potts,[18] who employed this procedure several times a day in postoperative surgical cases for the prevention of phlebothrombosis and subsequent pulmonary embolism. With this objective in mind, convalescent patients with myocardial infarction are instructed to take from eight to ten deep breaths while the legs are being flexed, at first passively and later actively, four times daily. Coronary thrombosis does not often repeat itself within a few weeks. An apparent second attack at such a time is usually due to pulmonary embolism, especially from leg veins. Dicumarol therapy apparently obviates such a complication, as it appears to discourage venous and intramural thromboses from forming (Nichol and Page[11]).

Myocardial failure associated with severe pulmonary edema and, sometimes, acute hepatic congestion is an occasional complication of myocardial infarction. Indications for its management include the judicious and careful use of digitalis and theophylline ethylenediamine, with adequate oxygen therapy.

MYOCARDIAL INFARCTION AFTER SURGICAL OPERATIONS

Coronary occlusion and myocardial infarction are not infrequently the cause of sudden death in subjects past middle life during surgical anesthesia and in the early postoperative period. The fall in blood pressure that characterizes such states presents an ideal situation for an already impaired coronary vessel to develop complete occlusion. This possibility justifies a painstaking preoperative appraisal of coronary efficiency and myocardial reserve, by careful inquiry into the middle-aged and older patient's cardiac response to the demands of his every day life, as well as a comprehensive survey and evaluation of the objective clinical, roentgenologic and electrocardiographic data. Naturally the proper choice of anesthetic with careful observation and management during anesthesia and in the immediate postoperative period is imperative. It would appear good judgment to reduce the time of surgical procedure to a minimum in any case of suspected coronary insufficiency. One must always bear in mind the danger of medical or surgical shock as a precipitating factor in the production of myocardial infarction, especially if the history of the patient suggests the presence of chronic coronary disease.

DIET AND ELIMINATION IN MYOCARDIAL INFARCTION

After three or four days of liquid diet the patient may receive a soft diet, which may include cooked cereals, weak tea, broth, gelatin, cottage cheese, applesauce, junket, baked potatoes and soft boiled eggs. No food is to be taken in large quantities. A small glass of milk or malted milk with a few wafers may be taken between meals if desired. Should the first week show evident progress without complications, a light general diet may be given, limiting the size of meals and minimizing fat, which tends to delay gastric emptying. Although increased blood cholesterol is not infrequently associated with coronary atherosclerosis, particularly in middle-aged subjects, a low fat diet alone does not reduce cholesterol levels. It appears to be the manner in which fat is disposed of and not the amount in the food that counts. Roughage should be limited because of its influence on gaseous distention. In general small meals, eaten slowly, and unaccompanied by much fluid, are preferable. Such a diet may include all the softer vegetables, eggs, lean meat, fowl or fish, toasted bread, cereals, tapioca, cooked ripe fruits, fruit juices and gelatin.

With regard to bowel movement, moderate elimination is to be procured with the least possible disturbance. Therefore the use of oil and agar preparations morning and evening, augmented by a glycerin suppository or small enema when necessary, is the optimum arrangement. The patient must be warned not to strain at stool or to try to help himself on or off the bedpan, as any extra exertion may present a serious hazard. When a chair commode presents less effort and stress, its cautious use is recommended.

REST IN THE TREATMENT OF CORONARY DISEASE

Arbitrary standardization of the time essential for complete rest in bed and avoidance of all physical activity after myocardial infarction is manifestly impossible. Acute coronary insufficiency frequently requires only a week or ten days of rest in bed, provided no area of actual infarction develops, which can be determined by the clinical course, sedimentation rate and electrocardiographic findings. Moderate degrees of [illegible] may only require three weeks of rest in bed, but the severer types require a minimum of from four to six weeks. Frequently the beneficial effects of rest in bed are offset by visitors, the intrusion of personal responsibilities or business worries, all of which should be shut off entirely from the patient's immediate horizon during his period of convalescence.

After recovery the most important phase in the restoration of reasonable functional capacity is adaptation to a lowered plane of activity, the development of a more philosophic outlook on life and the transition to a more tranquil and quiet existence. A degree of personal interest and patient guidance, tinctured with an understanding optimism is of greater benefit to a coronary convalescent than any program of medication, which on the whole is essentially protective in its objective.

The etiologic trinity of coronary disease consists of the predisposing, the precipitating and the perpetuating influences. The predisposing has already manifested itself in the afflicted subject—more often than not inscribed in the archives of his family history. Precipitating influences should be thoughtfully avoided and the lethal threat of stress and strain kept in mind. The perpetuating influences of coronary disease have been discussed, including overweight, injudicious habits of eating, drinking and smoking, uncurbed emotional proclivities along with unwarranted fatigue, all of which must be carefully and thoughtfully avoided in the interest of functional recovery and future welfare.

3604 Washington Boulevard.

ABSTRACT OF DISCUSSION

Dr. E. Sterling Nichol, Miami, Fla.: My comments will concern the treatment of acute coronary thrombosis with Dicumarol. The principal reason for using an anticoagulant in coronary thrombosis is to prevent embolic phenomena and extension of the initial thrombus or the occurrence of a second thrombus during the convalescence. The incidence varies, depending on whether one is dealing with clinical or autopsy data. To date 68 attacks occurring in 62 patients have been treated over the past three years. These were unselected, consecutive episodes, as it was not considered possible to tell which patient would need an anticoagulant. Although the idea of treating with Dicumarol only if the prothrombin activity is increased may be very good, there are other variables about which nothing is known. One cannot select a patient and say "he will have a small infarct." The results were not astounding but do compare favorably with published series. In the 68 attacks, 11 deaths gave a mortality of 16 per cent. No proven embolic phenomena occurred in the entire series. One patient may have died with pulmonary infarction, but no autopsy was allowed. In the 8 autopsies performed there were absolutely no signs of mural thrombi. Since autopsy statistics show that 50 per cent of all myocardial infarcts produce mural thrombi, it seems rather significant that in these 8 cases no mural thrombi were found. There were 38 first attacks with only 1 death, which is certainly a satisfactory ratio. Heparin will probably replace Dicumarol as an anticoagulant as soon as it becomes available in the Pitkin solution. I would like to take substantial exception to the idea that the best treatment for coronary thrombosis is "masterful inactivity." Comparison of mortality figures published over the past twenty years with the clinician philosophy reveals a striking parallel between the death rate and the inactivity!

Dr. William J. Kerr, San Francisco: In most patients with angina pectoris the major factor which is responsible for controlling the person's symptoms is getting more blood back to the heart. Methods have been devised which will aid in getting blood back to the heart by the use of a properly fitting elastic abdominal belt. In a period of ten years I have had hundreds of patients with angina pectoris, and most patients who fall in this general category are almost entirely relieved of attacks of anginal pain immediately, as soon as the belt is put on and properly adjusted. Most of the patients in this category no longer require any vasodilating drugs. Their weight is reduced as may be necessary, and later postural training is instituted. One of the most important factors in the treatment of the patient with an acute attack of coronary occlusion with infarction is the immediate relief of pain. One can give small doses of morphine intravenously immediately. The pain usually will stop while the morphine is being given. That is a great advance in the shortening of the attack of pain and thereby in the reduction of shock. It is the shock that often extends the zone of infarction. As Dr. Falk so well pointed out, many things are done that might even promote the extension of the infarcted area. It is essential that the patients start moving their arms and legs to prevent thrombosis in the veins. Do this as soon as possible. Many of the patients that I see in the second week or third week after an attack, when it is thought they are having a subsequent attack or an extension of the process, have only a pulmonary embolus resulting from a thrombosis in some part of the periphery. Vasodilators given in too large amounts may be harmful, because if there are narrowed coronary orifices or there is sufficient narrowing of the vessels in some part of the coronary system, should vasodilators cause peripheral dilatation and also result in dilatation of the coronaries, their purpose has been defeated. Temporary relief of pain may be obtained, but it may make patients worse. I have seen patients who have been taking 20 and 30 tablets of glyceryl trinitrate a day get worse and worse. By omitting these drugs entirely they may be almost completely relieved of their attacks. Some have spoken about the persistent pains in the shoulders of patients with coronary occlusion, assuming that this is on some reflex basis. There may be some patients in this category, but most of the patients I see have the frozen shoulder or bursitis or have shortening of the pectoralis muscles and latissimus dorsi and their tendons. That is the chief cause of painful shoulder, in my experience, and it is not due to some reflex from the diseased arm.

Dr. O. P. J. Falk, St. Louis: I believe every point has been covered by the generous discussion of Drs. Nichol and Kerr, for which I am grateful.

Eyestrain.—The most common factor determining eyestrain today, even to those with normal eyes, is insufficient or ill distributed illumination. There is a popular superstition that too much light is bad for the eyes and that harm results from work under artificial illumination: it is true that to look directly into the sun is dangerous since the infra-red rays may produce a retinal burn, but the eyes have been evolved to see and work most efficiently under illuminations comparable to that of diffuse daylight. There is no medical danger in artificial lighting; its usual fault is that it is either not nearly strong enough or so badly distributed as to induce the annoyance of glare. Summer sunlight at noon has an intensity of the order of 10,000 foot-candles, and on an overcast day it is about 1,000 foot-candles. Too often at work or when reading in the evening the illumination available is of the order of 1 or 2 foot-candles. No one can work or read efficiently or comfortably unless he sees what he is doing, and it is only necessary to turn on the available artificial light at noon to realize how poor a showing it makes and how great are the disadvantages under which our eyes habitually work.—Stewart Duke-Elder: Eyestrain, *Practitioner,* May 1947.

INFILTRATING CARCINOMA OF THE BLADDER

Application of Pathologic Observations to Clinical Diagnosis and Prognosis

HUGH J. JEWETT, M.D.
Baltimore

An inquiry into the reasons for the existing low survival rate in cases of infiltrating carcinoma of the bladder has disclosed four cardinal causes of failure with any method of treatment: (1) preexisting metastases; (2) preexisting extravesical extension; (3) intercurrent complications, and (4) incomplete destruction or extirpation of the primary growth.

It therefore seems obvious that accurate evaluation of the efficacy of any treatment in the total eradication of primary infiltrating tumors will depend first on the exclusion of metastasis and extravesical extension. The clinical application of our recent pathologic observations[1] to each individual patient now permits the exclusion or recognition of metastasis and extravesical extension in a fairly high percentage of cases and indicates the prognosis in most instances.

In 1944 the late Dr. Hugh H. Young proposed to me an analysis of the 1,400 cases of carcinoma of the bladder in the files of the Brady Urological Institute, for the purpose of ascertaining and standardizing the best method of treatment for each type of case. However, a preliminary survey made with the assistance of Dr. John Egan revealed the uselessness of such a program. First, in a large but uncertain number of cases the disease apparently had been hopelessly advanced and incurable at the time treatment was commenced, although many failures undoubtedly had resulted from incomplete destruction of a potentially curable tumor. Second, in some instances it seemed that cures had been attributed to certain methods of treatment although there was no conclusive evidence that the tumor had been infiltrating, beyond the impression gained from simple cystoscopic inspection. Therefore, since infiltration had not been established in every case and metastasis and extravesical extension had not been properly excluded, an accurate appraisal of treatment was not possible at that time.

The presence of metastasis or extravesical extension indicates an advanced stage of tumor, which is obviously incurable by any of the known methods of treatment. Four common reasons exist for the fact that these extensive tumors still comprise a large proportion of the vesical neoplasms seen in many urologic clinics. First, cancer of the bladder usually has an insidious onset and grows silently and sluggishly. Thus, the characteristic symptoms of hematuria and vesical irritability, of which one or the other appears in 80 per cent of the cases, may occur late. Second, the patients themselves, or their physicians, are often apathetic toward these warning symptoms for long periods of time. In a recent study[2] of 103 cases at the Johns

Hopkins Hospital, it was found that, prior to admission, 31 per cent of the patients had had symptoms from two and a half weeks to six months, and 50 per cent had had symptoms longer than one year. Third, after early and accurate diagnosis, the conservative treatment employed sometimes results in incomplete destruction of the tumor, and its growth may continue in the bladder wall beyond the range of cystoscopic visualization. Fourth, the diagnosis occasionally is missed in the case of a small, superficially infiltrating, sessile tumor, a specimen of which is not subjected to biopsy.

In summary, then, if one excludes an unnoticed recurrence caused by a persistent carcinogenic agent, two general causes exist for low curability: (1) late diagnosis, at which time there usually is extravesical spread, and (2) inefficacy of treatment, which allows a tumor without extravesical spread to persist, often unrecognized, in the bladder wall until it has extended extravesically or metastasized. Late diagnosis will be avoided only after more complete education of the members of the laity and the medical profession. Inefficacy of treatment will be recognized earlier and more frequently when the importance of an accurate appraisal of the entire pathologic picture is more fully appreciated. The efficacy of different methods of treatment under varying conditions will be demonstrated by the results obtained in the case of potentially curable tumors; that is, in cases in which there is no evidence of local extravesical extension or metastasis.

PATHOLOGY

In order to determine the conditions under which extravesical extension and metastasis occur, Dr. George H. Strong and I, in 1944, studied a series of 107 cases of infiltrating carcinoma of the bladder on which autopsies had been performed at the Johns Hopkins Hospital.[2a] We separated the cases into three groups (table 1): Group A comprised those in which penetration was limited to the submucosa. Group B consisted of those in which infiltration had extended into, but not through, the muscularis. Group C included all cases in which tumor cells had extended completely through the muscularis. We then determined in each group the number of cases with metastases, the number showing local lymphatic invasion only and the number with perivesical fixation of the mass. In each group the number without these three evidences of tumor spread gave us our figure for potential curability, which naturally represented only a theoretic possibility. Although the figure for potential curability is probably too high in each category,[3] the wide discrepancy between that in group B and that in group C is significant. Metastasis and extravesical extension are frequently associated with group C tumors and explain the low curability in this group following all methods of treatment.

Of the 89 cases comprising group C, regional or distant metastases were reported in 52. The cardinal sites and the frequency with which they were involved are indicated in table 2.

In 1945, the late Dr. S. S. Blackman of the Department of Pathology and I made a critical study of the histopathology of the tumors and their metastases in our series of autopsy cases.[4] The purpose of this study was twofold: First, to understand better the biologic characteristics of each individual tumor, and second, to see whether the correlation of the microscopic anatomy of the tumor with its degree of penetration of the bladder wall would have any bearing on the incidence of metastasis.

Without any preconceived ideas in regard to classification, we examined histologically 97 of our 107 autopsy cases, in which the pathologic material was suitable for detailed microscopic study. Only 48 of the primary tumors consisted of a homogeneous histologic pattern with practically the same degree of cellular differentiation throughout the available sections. Twenty-six manifested a homogeneous pattern but showed variation in the degree of cellular differentiation. In the remaining 21 cases the primary tumor was papillary in some places and epidermoid in others, and in some of these cases there was also a considerable variation in the degree of cellular differentiation.

TABLE 1.—*Relation of Curability to Depth of Infiltration in One Hundred and Seven Autopsy Cases*

	Infiltrating Carcinoma of Bladder		
	Group A	Group B	Group C
Number of cases	3	15	89
Metastases	0	1	52
Perivesical lymphatic invasion only	0	1	6
Perivesical fixation only	0	0	8
Potentially curable	3	13	23

TABLE 2.—*Cardinal Sites and Frequency of Metastasis in Group C, with Metastasis in Fifty-Two of Eighty-Nine Cases*

Site of Metastasis in 52 Cases	Number of Cases
1. Regional nodes	33*
2. Liver	26
3. Lungs	18
4. Vertebra, including pelvis	11
Other sites	20

Other sites involved in only 4 cases without involvement of sites 1, 2, 3 or 4.

* Nodes negative in 19.

Seventy-five of these cases were uniformly papillary, epidermoid or totally undifferentiated carcinoma throughout the available sections. However, we were able to demonstrate variation in the degree of cellular differentiation in 53 of the papillary and epidermoid carcinomas. Since variation in the degree of differentiation throughout a single tumor makes accurate classification on such a basis impossible, it seems obvious that infiltrating carcinomas of the bladder cannot be so classified with any degree of accuracy.

It therefore seems justifiable, from the evidence so far obtained, to segregate the tumors according to the three major categories, papillary, epidermoid and undifferentiated carcinoma, and in the papillary and epidermoid groups to record the poorly differentiated varieties. A section, however, which shows only a well differentiated carcinoma may be misleading, for in another area of the same tumor the cells may be totally undifferentiated.

The correlation of the microscopic anatomic structure of these tumors with the depth to which they had penetrated the bladder wall was of considerable significance. In group A (table 1) only 2 of the 3 cases were suitable for accurate classification. One was fairly well differentiated papillary carcinoma, and the other, poorly differentiated papillary carcinoma. Neither had metastasized.

[2a] Footnotes 1b and 2.

[3] A higher incidence of metastasis undoubtedly would have been found among these autopsy cases if all grossly normal regional lymph nodes had been sectioned.

[4] Jewett, H. J., and Blackman, S. S.: Infiltrating Carcinoma of the Bladder: Histologic Pattern and Degree of Cellular Differentiation in Ninety-Seven Autopsy Cases, J. Urol. **56**: 200-210 (Aug.) 1946.

Table 3 shows the histologic classification of the tumors comprising group B, and table 4, those comprising group C. A comparison of these two tables shows that undifferentiated carcinoma did not appear among the small number of cases comprising group B and epidermoid carcinoma predominated in group C. With these exceptions, however, the microscopic anatomy of the tumors in these two groups was much the same, but local lymphatic invasion and metastasis were infrequent in group B. It is possible that they would have been more frequent if the highly malignant, undifferentiated carcinomas had been present.

The ability to invade lymphatics depends on the malignancy of the tumor. But the presence or absence of lymphatic invasion in the case of a tumor of known malignancy is governed largely by accident. Since the tumors in group C are larger and the lymphatics in their environment are larger and more numerous,[1b] the opportunity for metastasis is greater in this group.

Table 3.—*Histologic Classification of Fourteen Tumors in Group B*

	Primary Tumor	Metastases
Papillary carcinoma	10	1
Epidermoid carcinoma	4	0
Undifferentiated carcinoma	0	0

In the papillary group 4 tumors were poorly differentiated, and 1 of these had metastasized.

In the epidermoid group 2 were poorly differentiated, and neither had metastasized.

Table 4.—*Histologic Classification of Eighty-One Tumors in Group C*

	Primary Tumor	Metastases
Papillary carcinoma	28	11
Epidermoid carcinoma	35	22
Undifferentiated carcinoma	18	15

In the papillary group 13 tumors were poorly differentiated, and 5 of these had metastasized. In the epidermoid group there were 22 cases in which the tumors were poorly differentiated, and of these 16 had metastasized.

It therefore may be said that the cellular appearance alone of an infiltrating carcinoma of the bladder indicates neither the presence nor the absence of metastasis. However, when the tumor is known to be deeply infiltrating, the poorly differentiated papillary carcinomas have metastasized in nearly half the cases,[3] the poorly differentiated epidermoid carcinomas in at least three fourths, and the undifferentiated carcinomas in practically all the cases.

For the clinical application of all these pathologic data, it is necessary that the diagnosis in each case be complete. The mere observation that a tumor exists in the bladder is not sufficient. The entire pathologic condition must be appraised.

SYMPTOMATOLOGY

The diagnosis will be made earlier when the patient and his physician fully appreciate the disastrous consequences of apathy toward slight hematuria or vesical irritability, especially in patients over 40 years of age. In a previous report [2] it was emphasized that cancer of the bladder claims 3.2 per cent of all persons dying of malignant disease. In this same report it was shown that, in our series of 107 cases, the presenting symptom was hematuria in 66 (61.7 per cent) and vesical irritability (frequency, urgency and pain on urination, usually with pyuria) in 34 (31.8 per cent). One or the other, but not both, of these 2 symptoms was present in 87 (81.3 per cent) of the cases.

DIAGNOSIS

The diagnosis is necessarily incomplete unless three specific procedures are carried out. These are cystoscopy, biopsy and bimanual palpation.

1. *Cystoscopy.*—The recognition of tumor of the bladder usually rests on cystoscopic inspection of the gross characteristics of that portion of the mass lying within range of visualization. Its size, location and margins must be noted. Most cases are recognized as pedunculated or sessile and may or may not be associated with edema, necrosis and ulceration with fibrin or calcareous deposition and hemorrhage. Papillary cystitis, bullous edema and simple ulceration occasionally make accurate diagnosis difficult.

2. *Biopsy.*—In questionable cases the diagnosis is established by a properly taken biopsy specimen. A good sized piece of tissue, including some muscularis, should be removed under anesthesia, preferably with a cold rongeur. In the case of pedunculated tumors the piece should be taken immediately beneath the base of the pedicle (figs. 1, 2 and 3). In this case a specimen of superficial tissue for biopsy would have led to the diagnosis of benign papilloma, whereas beneath it, in the wall of the bladder, lay a moderately differentiated epidermoid carcinoma.

The inclusion of some muscularis in the properly taken biopsy specimen establishes the presence or absence of infiltration as well as the diagnosis of tumor. The clue to the prognosis, however, is not furnished by biopsy alone, for it must be borne in mind that this tissue represents only a relatively small part of the whole tumor. Poorly differentiated carcinomas, when deeply infiltrating, have metastasized in the majority of cases. When they are superficially infiltrating, metastases from these tumors are infrequent. Carcinomas which appear well differentiated in biopsy sections may actually be poorly differentiated in other areas.[4]

3. *Bimanual Palpation.*—With the diagnosis made, and with infiltration established by biopsy, the next step is to determine the extent to which the tumor has penetrated the bladder wall. Since deeply infiltrating tumors in over 80 per cent of the cases cause stony, hard induration, and since superficially infiltrating tumors practically never cause stony induration, the clinical segregation of these two groups of cases will depend largely on accurate palpation. In the male, this is best accomplished rectoabdominally under anesthesia deep enough to achieve complete muscular relaxation.[5] In the female, simple pelvic examination usually suffices.

The significance of the observations is as follows:

1. Extravesical extension, with or without fixation, is readily recognized and indicates incurability.

2. Stony induration without evidence of extravesical extension indicates the presence of metastasis in the

---

[5] Jewett, H. J.: Carcinoma of the Bladder: The Importance of Recto-Abdominal Palpation Under Anesthesia in the Selection of Cases for Total Cystectomy, J. Urol. **49**: 34-41 (Jan.) 1943.

great majority of poorly differentiated tumors and in nearly all undifferentiated tumors.

3. Rubbery induration without extravesical extension denotes a slightly lower incidence of metastasis. In cases of this type, if undifferentiated carcinoma can be excluded, complete destruction or extirpation of the primary growth should result possibly in a higher percentage of cures.

4. No palpable induration, with the patient under completely satisfactory anesthesia and relaxation, indicates in practically all cases absence of metastasis and therefore a high potential curability.

Roentgenograms of chest, spine and pelvis, excretory urography and the examination at laparotomy of the bladder, regional lymph nodes and liver complete the appraisal of the gross pathologic condition.

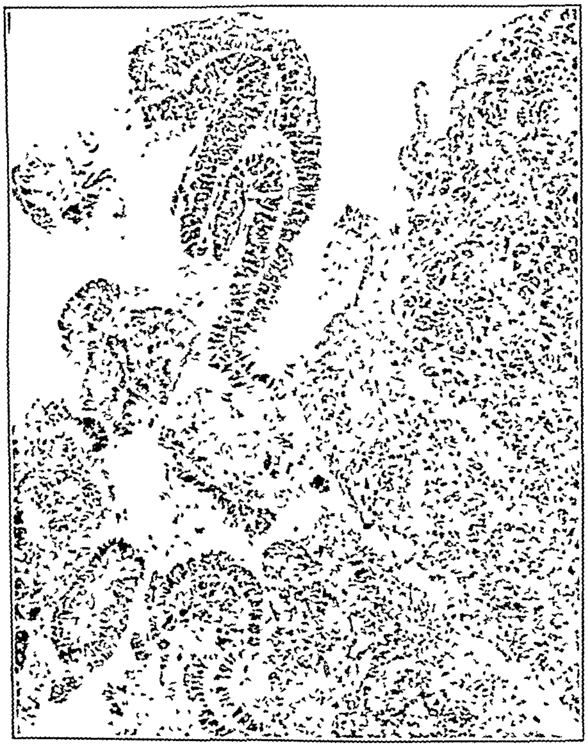

Fig 1 —Photomicrograph of a section of bladder wall showing papillomas on the surface and infiltrating carcinoma in the underlying tissues

In cases without metastasis and extravesical extension a good prognosis presupposes complete eradication of the tumor of the bladder and early, adequate treatment of future recurrences.

SUMMARY

Incurability in infiltrating carcinoma of the bladder depends largely on metastasis and extravesical extension. These may occur before, during or after treatment. The efficacy of the treatment can be evaluated only when these factors can be excluded before treatment. This can be done with a fair degree of accuracy only by clinical appraisal of the entire pathologic condition, of which the most significant component is the extent to which the tumor has penetrated the bladder wall.

Deeply infiltrating tumors are associated with a high incidence of metastasis and as a rule cause stony induration, which usually can be felt by bimanual palpation with the patient under anesthesia. When tumors of this type are poorly differentiated they probably have metastasized in nearly all the cases.

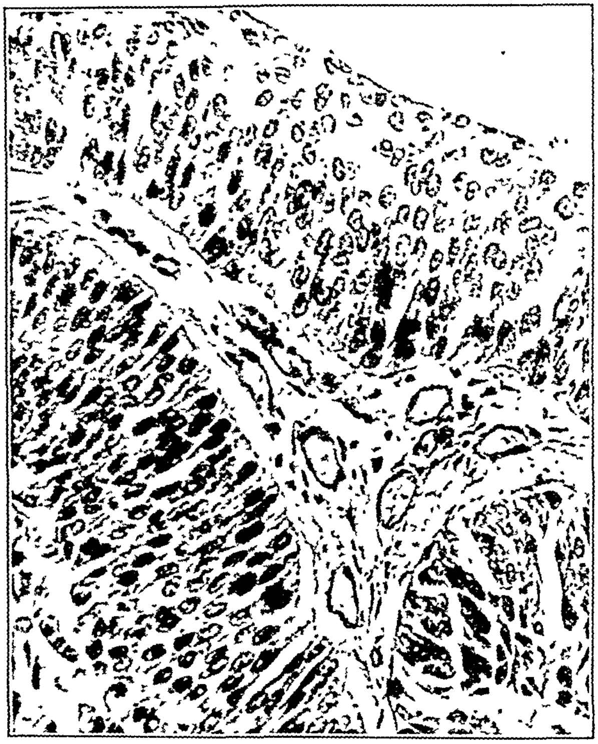

Fig 2.—High power view of section of benign papilloma in fig. 1.

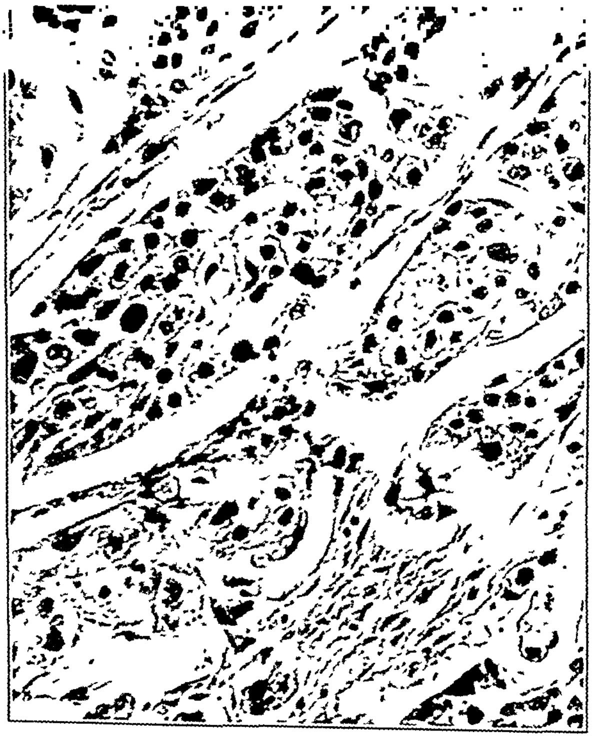

Fig. 3 —High power view of moderately differentiated epidermoid carcinoma in the bladder wall beneath the benign papilloma in figs 1 and 2

Superficially infiltrating tumors produce in the bladder wall a consistency varying from normal to rubbery. In these tumors the incidence of metastasis is low except perhaps in the case of undifferentiated carcinomas.

CONCLUSIONS

In infiltrating carcinoma of the bladder an evaluation of all the obtainable data concerning its gross and microscopic characteristics will indicate, with a fair degree of accuracy, the presence or absence of metastasis and extravesical extension. When these are absent, a good prognosis will depend on complete destruction or extirpation of the tumor and adequate treatment of future recurrences.

ENDOSCOPIC TREATMENT OF TUMORS OF THE BLADDER

HAROLD P. McDONALD, M.D.
ALEXANDER J. FILIP, M.D.
and
DAVID C. WILLIAMS Jr., M.D.
Atlanta, Ga.

The purpose of this paper is to present some of the advantages of the endoscopic method of resection of tumors of the bladder. It is by no means proposed that all such tumors be treated by endoscopic means. It is recognized and admitted that open operation is the method of choice in certain types of tumors of the bladder, especially if they are located in the free portion of the bladder. In the majority of these tumors, however, treatment by means of endoscopic surgery offers more satisfactory results than open surgery.

In successful management of tumors of the bladder the most important factor is early diagnosis. Tumors which are discovered in an early stage are more likely to be curable by endoscopic means. Tumors found early are less likely to be infiltrating, are more likely to be pedunculated. Tumors found early are less likely to be malignant. Although these facts have been emphasized repeatedly, patients are still being seen with tumors of the bladder who have had hematuria for months and in some instances for a year or longer. The family physician must insist on immediate cystoscopic examination of the patient when blood appears in the urine. To fail in this is to be guilty of malpractice. The value of early endoscopic examination to determine the source of blood in the urine cannot be overemphasized. The danger of delay cannot be overemphasized. We must continue to call attention to this fact again and again.

In considering the treatment of tumors of the bladder by endoscopic means, two main groups are recognized. In the first group we place tumors that are considered curable. In this group are nonmalignant papillomas, pedunculated malignant papillomas, small elevated carcinomas either noninfiltrating or of the early infiltrative type, possibly only through the mucosa.

In the second group we place tumors that are not considered curable. In this group are extensive malignant papillomas, extensive carcinomas and recurrent nodules following previous operative intervention. Treatment in this group is palliative, but, as will be shown, is by no means hopeless.

When seen sufficiently early practically all tumors of the bladder fall into group 1 and are curable. Endoscopic resection of the tumor with wide and deep destruction of the base is the method of choice in the treatment of these early tumors.

Technic: The Stern-McCarthy resectoscope activated by the electrosurgical unit is the apparatus customarily used. A short beaked sheath is preferable to the standard length sheath.

The end of the standard resectoscope sheath projects over and beyond the loop and often prevents thorough resection of a tumor mass, especially when it is located in a concave portion of the bladder. With the end of the beak cut off or shortened the operator can get the loop of the resectoscope closer to the tumor and can thoroughly resect and even excavate the base of the tumor. The resection of the tumor base should be extended through the mucosa and at least half through the muscle of the bladder. The resection should extend ¼ to ½ inch (0.5 to 1 cm.) wide on all sides beyond the base of the tumor. Fulguration of this area should be thorough. Rest of the bladder by insertion of a retention catheter should be maintained for three to four days, after which the catheter may be removed. From six weeks to two months after the resection the bladder should be inspected. The whole bladder as well as the previously resected area should be examined. Regular inspection must be made at three month intervals for three years and then at four month intervals for two or more years longer. An added precaution is yearly inspection of the bladder even after five years have elapsed without recurrence. Provided no recurrences are observed in this time the patient may be considered cured. Destruction by fulguration of any recurrent small tumor masses can usually be performed in the office. As a rule the recurrent tumor does not get sufficiently large between inspections to necessitate more radical treatment.

Examples of tumors of the bladder entirely cured by endoscopic resection are numerous in the experience of almost every urologist. A few cases will suffice to illustrate.

Case 1.—Mr. J. E. H., aged 39, came in three weeks after blood was noticed in the urine. A small tumor in the left side of the bladder just outside the trigone was resected, and the base was fulgurated. Microscopic examination of the tissue showed papillary carcinoma, grade 2. Regular cystoscopic examinations have been made for six and a half years. No recurrence has been found.

Case 2.—Mr. W. H. S., aged 63, first noticed blood in the urine six weeks before coming in for examination nine years ago. Cystoscopic examination revealed a mass approximately 2 cm. in diameter just lateral to the right ureter. The lateral lobe of the prostate gland was seen to be pressing into the urethra from each side. Complete resection and fulguration of the base of the tumor was done. The prostate gland was resected at the same time. Microscopic studies showed that the tumor of the bladder was a papillary adenocarcinoma, grade 3. The prostatic tissue showed benign hyperplasia. This patient came back for regular cystoscopic inspections every three months for a period of three years. No recurrence was noted in this time. A report received from him two weeks ago states that he has moved to Florida and is well.

Case 3.—Mr. L. P. M., aged 50, came in six years ago with blood in the urine of two months' duration. Examination revealed a tumor in the bladder above and lateral to the right ureter. Endoscopic resection of the tumor was done, and the base of the tumor was fulgurated thoroughly. Microscopic study revealed papillary carcinoma, grade 2. Cystoscopic examination six weeks later showed a slight ulceration still present at the site of the tumor. One month later the tumor site, although healed was fulgurated. Regular cystoscopic inspections have been made since, the last time two months ago. No tumor or evidence of tumor has been found. The importance of regular cystoscopic inspections is again demonstrated.

Read in a symposium on "Urinary Vesical Tumors" before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

For extensive tumors of the bladder endoscopic resection is often the means of palliative treatment, sometimes even after the metastases have occurred. Bleeding may be checked, cystitis lessened and function of the bladder improved by endoscopic resection of tumor masses, even though cure or control of the tumor is impossible. The next 4 cases are examples of palliative treatment.

Case 4.—Mr. E. D., aged 67, had been bleeding off and on for over twelve months. Examination revealed a large seminecrotic tumor mass almost filling the left side of the bladder. A cystogram after the injection of air was made, which showed that most of the bladder was occupied by the tumor. There was also grade 2 enlargement of the lateral lobes of the prostate. Metastatic areas were noted by roentgen examination in the lower part of the spine and sacrum. Endoscopic resection of the tumor mass and of the prostate gland was performed. The microscopic sections exhibited papillary carcinoma, grade 3. The prostatic tissue showed benign hyperplasia with fibrosis. This patient experienced great relief for over a year. This improvement and relief justified palliative endoscopic treatment for this man.

Case 5.—Mr. A. M., aged 50, was seen twenty-nine years ago with hematuria of two to three months' duration. A papilloma was found in the bladder and fulgurated with the old high frequency current by my superior, the late Dr. Edgar Ballenger. This patient had recurrences from time to time, and during the succeeding twenty-six years 21 fulgurations were done. When last seen four years ago this man was 75 years of age and without evidence of tumor in the bladder.

Case 6.—Miss R. C., aged 50, noticed blood in her urine eight months before being referred to us by her family physician. It is hard to understand the delay in reference of this case. Cystoscopic study showed extensive malignant tumor involving the dome and upper half of the lateral wall of the bladder. A subtotal cystectomy was performed, and all demonstrable tumor was removed. Microscopic studies revealed epidermoid carcinoma, grade 3. Three months later small recurrences were observed on inspection of the bladder. Endoscopic fulguration was performed in the office. This procedure was repeated eight weeks later, but the tumor was observed to be progressing rapidly, and endoscopic resection of the recurrent masses was then done with the patient under spinal anesthesia in the hospital. Further recurrences may be expected and may be treated by endoscopic resection as before. Provided regular inspections of the bladder are continued, these recurrences may be kept under control.

Case 7.—Mr. E. W. S., aged 47, came in three years ago with a history of recurrent bleeding for twelve months. His family physician told him repeatedly to come in for cystoscopic examination during this twelve months. When he did come in the tumor was about the size of a lime and covered an area in the right side of the base of the bladder. The tumor was removed transurethrally, and the base thoroughly cauterized. He stayed away almost twelve months, and the tumor recurred. Another endoscopic resection was performed, and the patient has reported for inspection of the bladder regularly every three months since. A few weeks ago cystoscopic examination showed a small recurrent tumor mass near the site of the original tumor. The mass was small and was fulgurated in the office. It will be necessary for this man to continue to have regular inspections.

SUMMARY AND CONCLUSIONS

Endoscopic resection is one of the important methods used to control and cure tumors of the bladder. Palliative resections are useful when tumors are recognized late; they are justified in that morbidity is reduced and comfort and relief is afforded many patients with incurable tumors of the bladder. The highest degree of success is afforded when the tumor is recognized early. The importance of early diagnosis therefore is impossible to overemphasize. Hematuria demands immediate investigation as to the source. The family physician must insist on this investigation. Regular cystoscopic inspections at least four times a year are essential and must be insisted on for all patients who have had operations, whether open or endoscopic for tumor of the bladder. This policing job is a must for patients with tumor of the bladder.

57 Forsyth Street, North West.

A COMPARISON OF RADIATION AND SURGERY FOR CANCER OF THE BLADDER

VICTOR F. MARSHALL, M.D.
New York

Apparently there are no spontaneous cures of cancer of the bladder. Forber[1] reported the average duration of life, presumably from the time of diagnosis, of 33 untreated patients to be 18.8 months, while Welch and Nathanson[2] in a series of 28 untreated patients found that 14 had died in fourteen months, 21 had died in thirty months, and 25 had died by the end of five years. The average age of 302 patients of this series was 59.4 years, for which age group statistics compiled by a life insurance company for the general population show a life expectancy of 15.49 years; approximately 88 per cent survive five years. It is obvious, therefore, that untreated cancer of the bladder is a highly fatal disease. Though perhaps not so rapidly lethal as pulmonary and gastric cancer, the situation existing five years after diagnosis is nearly the same. Furthermore, the morbidity associated with tumors of the bladder is great. The fact that there are numerous methods for treatment suggests that none are highly successful. In general, the therapeutic procedures can be divided into two classes: those in which reliance is placed on radiation, and those in which reliance is placed on surgical procedures. No doubt these methods will be improved on, and endocrine and chemical therapy may be added as knowledge of these methods of treatment increases.

Radiation therapy has much to recommend it. Since some cancers have been found definitely radiosensitive, and since the bladder is sufficiently accessible for a reasonable dosage to be delivered, treatment by radiation seems to offer hope on a theoretic basis. Furthermore, some vesical neoplasms have been cured by radiation in actual experience. The immediate mortality is low, and with radon seeds and x-ray machines readily available, the method is convenient for both physician and patient. If radiation is given to the ambulatory patient the turnover in the hospital census may be rapid, allowing a larger number of patients to be treated in the surgeon's time, as compared with the time required for purely surgical therapy. The suffering ambulatory patient is usually less of a burden to the urologist than the miserable inpatient whom he must see daily. Mastery of the technic of radiation is not difficult to acquire by consulting one of several published plans, which are based on sound physical principles; or, even more easily, the precarious respon-

sibility for treating these patients may be divided with a radiologist! The surgical skill necessary for the implantation of radon seeds, or radium, into the bladder is rudimentary. The operative time is brief. With all these qualities the radiation method of treating carcinoma of the bladder appears most tempting. Accordingly, it has been popular. Now that a fairly large group of patients has been enthusiastically treated by radiation, it seems only proper to take stock of the results obtained. What percentage of the whole number of patients, whose disease was accurately diagnosed, survived five years? How *many not only survived* but were apparently free of disease five years after diagnosis, when they had been treated by radiation? What was the morbidity? Did patients die of the treatment rather than in the natural course of the disease?

Three hundred consecutive cases of neoplasms of the bladder from 1932 to 1938 inclusive were under the care of the Cornell staff at the New York and Memorial hospitals. In all these cases the lesions have been biopsy-proved to be neoplasm, although it is possible that a few papillomas with atypical features may have crept into the group classified as cancer. Incidentally, the results obtained in cases of benign papillomas were much poorer than anticipated. The pathologic diagnoses were made by Dr. N. C. Foot of the New York Hospital and Drs. Fred W. Stewart and Frank Foote at the Memorial Hospital. In a large number of cases, including all the possible cures, the slides were reexamined. In many instances the slides were examined by all three pathologists with little essential variation in diagnosis. These pathologists do not call simple papilloma grade 1 cancer, and in general their opinions label the grades lower than do many pathologists, including the Bladder Tumor Registry. In fact the use of the Bladder Tumor Registry reports would definitely improve the results in this study by allowing the inclusion of lower grade lesions in higher grades and by allowing many papillomas to be grouped as cancer. No known case was excluded in which a diagnosis of vesical cancer was made, except for approximately 3 to 5 cases, constituting 1 per cent or less, in which the charts of the patients were so incomplete as to be virtually worthless for study. This small exception is more than favorably offset by the inclusion of a few long-term cures being currently followed: that is, cases first observed before 1932 in which the patients have been seen during the last three years. Roentgen, radium and radon therapy were readily available in a variety of forms, although supervoltage radiation was not then available. An early impression of the results obtained by supervoltage radiation, however, is that there is little difference from the results obtained before its use. In brief, the method used was the implantation of radon seeds into the base of the tumor, usually after the excision of the more superficial portion, followed by roentgen radiation delivered around the pelvis. Gold radon seeds, averaging 1.5 millicuries each, were placed 1 cm. equidistant from each other and approximately 0.5 to 1 cm. beneath the surface and into an area 1 to 2 cm. wide of normal-appearing tissue about the margin of the tumor. Technical considerations mainly determined whether the implantation should be suprapubic or cystoscopic, though cystotomy was favored as allowing greater accuracy, particularly for the larger lesions. Roentgen radiation was usually given to six large portals around the pelvis by a 200 or 250 kilovolt machine at 50 to 70 cm. target skin distance, approximately 2,000 r in air to each portal. Recurrences were treated by additional radiation, either radon seeds, roentgen radiation, or both. The end results do not seem to have clear correlation to variations in technic but rather do seem to have correlation to the general size and type of tumor, as will presently be pointed out. Occasionally, roentgen radiation was omitted altogether, but the reason for this is not evident, in view of the enthusiasm for this method which prevailed during that time.

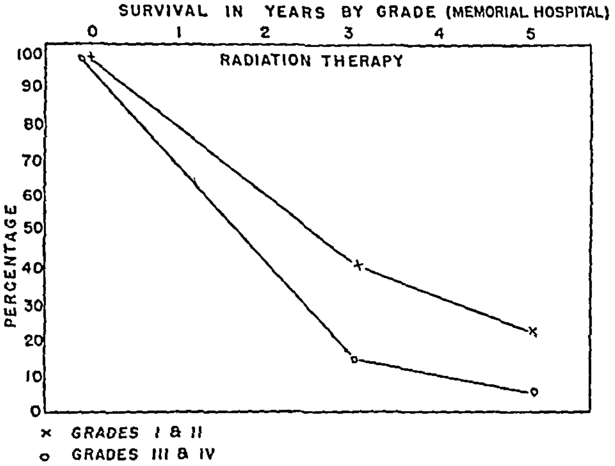

Chart 1.—Survival after radiation therapy.

Table 1.—*Comparison of Survival Rates*

	General Population for Same Age	Cancer of the Bladder	
		No Treatment	By Radiation
Average survival	15 years	18.8 mo.	24.5 mo.
Percentage surviving 5 years	88	10	17.3
Percentage of 5 year successful results	—	0	5-6

Of the 300 patients with cancer of the bladder only 52, or 17 per cent, were known to have survived sixty months or more after the time of the diagnosis. Two hundred and forty-two, or 80.6 per cent, were known to be dead at some time in the follow-up, and on only 24, or 8 per cent, there was no reliable record in regard to the five year survival. Accordingly, the follow-up is fairly accurate for this category, so that by the radiation methods used in the thirties a 15 to 20 per cent five year survival was obtained.

Table 2.—*Two Hundred and Fifty-Five Cancers (Not Papilloma) Graded at Memorial Hospital*

11.4% were grade 1
33.3% were grade 2
45.8% were grade 3
9.4% were grade 4

Of the 300 patients with vesical cancer 6 were dead of other causes before the fifth year anniversary, without evidence of neoplasm at the time of death—2 per cent. Three were lost track of, without recurrence—1 per cent. These 9 cases are classified as of indeterminate result, leaving 291 cases on which to base the calculations in this study. Known to be dead as a result of the disease, its complications or treatment are 232, or 79.7 per cent. Twenty-one with disease were lost track of and are considered therapeutic failures; and 11 were living at the five year anniversary, but with disease. Thus the results in 264 of the determinate group of 291 cases are considered failures at the time of the five year anniversary—90.8 per cent. Twenty-seven patients, or 9.2 per cent, were alive and by fair evidence had no neoplasm at the end of five years, although it cannot be said that each of these 27 patients would stand a severe reexamination as to whether they were unquestionably cured. Ideally, there should be no signs or symptoms of tumor of the bladder by all methods of examination, including cystoscopy, on or shortly after the five year anniversary. Practically, the record indicated that there was no tumor found at the last examination, that the patient was definitely alive at the end of five years and that the patient's condition on that anniversary did not suggest persistent or recurrent tumor. The majority of the patients who survived five years were seen in person, but a few answered letters. Almost none of these 27 patients could be regarded as free of disease throughout the five year period, but rather it is meant to say that on the date five years after diagnosis of the disease the record would permit reasonable interpretation of the patient's condition as free of neoplasm. In at least 5 instances the records were not completely satisfactory, but by liberal allowances the patients could be termed free of disease. In 3 or more cases there is some doubt of the pathologic diagnosis of cancer as opposed to papilloma. Three patients were apparently free of disease because of a total cystectomy performed after the failure of radiation therapy. At least 5 have died since the five year anniversary, and some of these had definite symptoms of cancer. In other words, only 10 to 15 of the 27 cases of supposed cure can stand under cross examination as cures most likely effected by radiation: approximately 6 per cent of the entire series.

Table 3.—*Radiation Survival by Grade (Complete Follow-Up for Three Years or More)*

	Average, Mo.	3 Years or More Percentage at
Grades 1 and 2 (107 cases)...............	35.1	40.2
Grades 3 and 4 (132 cases)...............	21.1	15.1

During the era of enthusiasm for radiation, the high morbidity is attested by several items. In 102 consecutive cases at the New York Hospital, 16 patients, or 15 per cent, required unforeseen operations on the upper part of the urinary tract for acute serious processes and not for the autonephrectomy type of lesion. The originally held opinion that radon seeds placed near a ureteral orifice would not cause obstruction, and that if obstruction did occur this would be due to tumor, has been disproved many times; especially has it been the more frequently disproved as follow-up intravenous pyelograms have been made. The vast majority of patients had severe symptoms of cystitis, many lasting several months and some, several years. Contracted bladders, calcific incrustations, actual vesical calculi and poorly healing cystotomy wounds were not unusual. In at least 2 patients there developed fecal fistulas, and in 4 communications developed between the bladder and the vagina. Radiation proctitis, varying degrees of incontinence, late radiation ulcerations of the skin and chronic edema of the genitalia, while not common, were by no means infrequent. Diversion of the urinary stream for symptomatic relief seemed to be performed more commonly as the series increased, but even so 3 patients had cystectomies performed to prevent exsanguination after radiation therapy and urinary diversion had been accomplished. Of course, metastases and local extension of cancer were commonly seen. These considerations should not imply that all this morbidity resulted from the radiation rather than from the disease, but certainly an extensive morbidity was not avoided by radiation, and probably some was added.

A problem which frequently arose was the difficulty of determining whether tumor still existed beneath the inflammation and slough. This is also one of the difficulties encountered in compiling the statistics.

Undoubtedly some of the patients died from the treatment rather than from the disease, as some mortality, however slight, results from almost any form of treatment. How frequently this untoward situation occurred is difficult to say, but some known facts do throw a light on the matter. Of 53 autopsies, including a few apparently accurate reports on cases from other institutions, no metastases were found in 23; 27 did have metastases, while in 3 no statement in this regard appeared in the record. In other words nearly half of the fatal and completely studied cases in these institutions, which are not primarily for terminal care, did not have metastases sufficiently developed to be recognized at autopsy. At any rate, nearly one half of these dead patients died not of carcinomatosis but primarily of sepsis and obstruction of the upper part of the urinary tract, except for the few dying of such relatively unconnected causes as embolism and coronary thrombosis. It seems apparent, therefore, that the rate of survival would have been definitely improved if the upper portion of the urinary tract had been protected from obstruction and infection. In fact, this protection was lacking to such an extent that a significant number of patients died from this lack, some of whom might otherwise have been cured. If a method could be devised for protecting the kidneys, more cures and certainly longer survivals could be accomplished, whether the treatment of the neoplasm was by radiation therapy or by surgical intervention. Penicillin and sulfonamide drugs will be valuable aids but hardly the main solution to the problem, as mechanical obstructions and sloughing neoplastic tissue are the natural prime causes of infection in this disease, to which the trauma of radiation is so often added.

Hospital mortality after the implantation of radon seeds by cystotomy was approximately 5 per cent, which indicates that only a small portion of the poor results can be attributed to the surgical procedures involved, especially as one remembers that death after operative intervention in a patient with cancer does not by any means indicate that death was due directly to the surgical maneuvers. Since only 15 to 20 per cent of the patients survived five years and only 6 per cent were cured in five years, the average survival time for the radiation-treated cases should be expected to be low. As has already been pointed out from the literature, the average survival, apparently from the time of diagnosis, of untreated patients was nearly nineteen months. The life expectancy for the general population of the same age was approximately fifteen years. With 287 patients (some more recent than 1938) having a complete follow-up of three years or more, death before that time being considered complete also, the average survival was 27.1 months from sibility for treating these patients may be divided with a radiologist! The surgical skill necessary for the implantation of radon seeds, or radium, into the bladder is rudimentary. The operative time is brief. With all these qualities the radiation method of treating carcinoma of the bladder appears most tempting. Accordingly, it has been popular. Now that a fairly large group of patients has been enthusiastically treated by radiation, it seems only proper to take stock of the results obtained. What percentage of the whole number of patients, whose disease was accurately diagnosed, survived five years? How many not only survived but were apparently free of disease five years after diagnosis, when they had been treated by radiation? What was the morbidity? Did patients die of the treatment rather than in the natural course of the disease?

Three hundred consecutive cases of neoplasms of the bladder from 1932 to 1938 inclusive were under the care of the Cornell staff at the New York and Memorial hospitals. In all these cases the lesions have been biopsy-proved to be neoplasm, although it is possible that a few papillomas with atypical features may have crept into the group classified as cancer. Incidentally, the results obtained in cases of benign papillomas were much poorer than anticipated. The pathologic diagnoses were made by Dr. N. C. Foot of the New York Hospital and Drs. Fred W. Stewart and Frank Foote at the Memorial Hospital. In a large number of cases, including all the possible cures, the slides were reexamined. In many instances the slides were examined by all three pathologists with little essential variation in diagnosis. These pathologists do not call simple papilloma grade 1 cancer, and in general their opinions label the grades lower than do many pathologists, including the Bladder Tumor Registry. In fact the use of the Bladder Tumor Registry reports would definitely improve the results in this study by allowing the inclusion of lower grade lesions in higher grades and by allowing many papillomas to be grouped as cancer. No known case was excluded in which a diagnosis of vesical cancer was made, except for approximately 3 to 5 cases, constituting 1 per cent or less, in which the charts of the patients were so incomplete as to be virtually worthless for study. This small exception is more than favorably offset by the inclusion of a few long-term cures being currently followed: that is, cases first observed before 1932 in which the patients have been seen during the last three years. Roentgen, radium and radon therapy were readily available in a variety of forms, although supervoltage radiation was not then available. An early impression of the results obtained by supervoltage radiation, however, is that there is little difference from the results obtained before its use. In brief, the method used was the implantation of radon seeds into the base of the tumor, usually after the excision of the more superficial portion, followed by roentgen radiation delivered around the pelvis. Gold radon seeds, averaging 1.5 millicuries each, were placed 1 cm. equidistant from each other and approximately 0.5 to 1 cm. beneath the surface and into an area 1 to 2 cm. wide of normal-appearing tissue about the margin of the tumor. Technical considerations mainly determined whether the implantation should be suprapubic or cystoscopic, though cystotomy was favored as allowing greater accuracy, particularly for the larger lesions. Roentgen radiation was usually given to six large portals around the pelvis by a 200 or 250 kilovolt machine at 50 to 70 cm. target skin distance, approximately 2,000 r in air to each portal. Recurrences were treated by additional radiation, either radon seeds, roentgen radiation, or both. The end results do not seem to have clear correlation to variations in technic but rather do seem to have correlation to the general size and type of tumor, as will presently be pointed out. Occasionally, roentgen radiation was omitted altogether, but the reason for this is not evident, in view of the enthusiasm for this method which prevailed during that time.

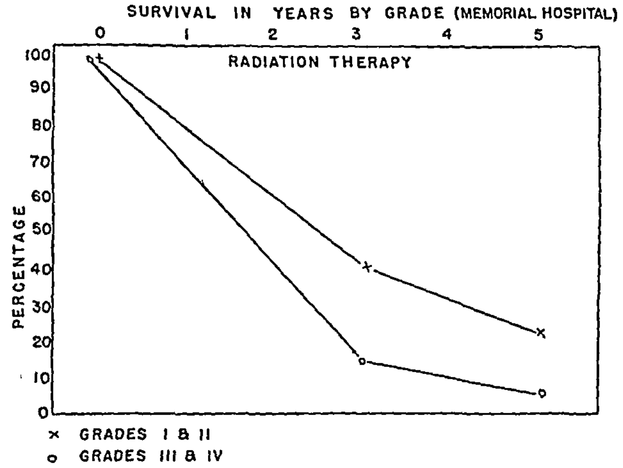

Chart 1.—Survival after radiation therapy.

Table 1.—*Comparison of Survival Rates*

	General Population for Same Age	Cancer of the Bladder	
		No Treatment	By Radiation
Average survival..................	15 years	18.8 mo.	24.5 mo.
Percentage surviving 5 years.......	88	10	17.3
Percentage of 5 year successful results........................	—	0	5-6

Of the 300 patients with cancer of the bladder only 52, or 17 per cent, were known to have survived sixty months or more after the time of the diagnosis. Two hundred and forty-two, or 80.6 per cent, were known to be dead at some time in the follow-up, and on only 24, or 8 per cent, there was no reliable record in regard to the five year survival. Accordingly, the follow-up is fairly accurate for this category, so that by the radiation methods used in the thirties a 15 to 20 per cent five year survival was obtained.

Table 2.—*Two Hundred and Fifty-Five Cancers (Not Papilloma) Graded at Memorial Hospital*

11.4% were grade 1	45.8% were grade 3
33.3% were grade 2	9.4% were grade 4

Of the 300 patients with vesical cancer 6 were dead of other causes before the fifth year anniversary, without evidence of neoplasm at the time of death—2 per cent. Three were lost track of, without recurrence—1 per cent. These 9 cases are classified as of indeterminate result, leaving 291 cases on which to base the calculations in this study. Known to be dead as a result of the disease, its complications or treatment are 232, or 79.7 per cent. Twenty-one with disease were lost track of and are considered therapeutic failures; and 11 were living at the five year anniversary, but with disease. Thus the results in 264 of the determinate group of 291 cases are considered failures at the time of the five year anniversary—90.8 per cent. Twenty-seven patients, or 9.2 per cent, were alive and by fair evidence had no neoplasm at the end of five years, although it cannot be said that each of these 27 patients would stand a severe reexamination as to whether they were unquestionably cured. Ideally, there should be no signs or symptoms of tumor of the bladder by all methods of examination, including cystoscopy, on or shortly after the five year anniversary. Practically, the record indicated that there was no tumor found at the last examination, that the patient was definitely alive at the end of five years and that the patient's condition on that anniversary did not suggest persistent or recurrent tumor. The majority of the patients who survived five years were seen in person, but a few answered letters. Almost none of these 27 patients could be regarded as free of disease throughout the five year period, but rather it is meant to say that on the date five years after diagnosis of the disease the record would permit reasonable interpretation of the patient's condition as free of neoplasm. In at least 5 instances the records were not completely satisfactory, but by liberal allowances the patients could be termed free of disease. In 3 or more cases there is some doubt of the pathologic diagnosis of cancer as opposed to papilloma. Three patients were apparently free of disease because of a total cystectomy performed after the failure of radiation therapy. At least 5 have died since the five year anniversary, and some of these had definite symptoms of cancer. In other words, only 10 to 15 of the 27 cases of supposed cure can stand under cross examination as cures most likely effected by radiation: approximately 6 per cent of the entire series.

Table 3.—*Radiation Survival by Grade (Complete Follow-Up for Three Years or More)*

	Average, Mo.	3 Years or More Percentage at
Grades 1 and 2 (107 cases)...............	35.1	40.2
Grades 3 and 4 (132 cases).........	21.1	15.1

During the era of enthusiasm for radiation, the high morbidity is attested by several items. In 102 consecutive cases at the New York Hospital, 16 patients, or 15 per cent, required unforeseen operations on the upper part of the urinary tract for acute serious processes and not for the autonephrectomy type of lesion. The originally held opinion that radon seeds placed near a ureteral orifice would not cause obstruction, and that if obstruction did occur this would be due to tumor, has been disproved many times; especially has it been the more frequently disproved as follow-up intravenous pyelograms have been made. The vast majority of patients had severe symptoms of cystitis, many lasting several months and some, several years. Contracted bladders, calcific incrustations, actual vesical calculi and poorly healing cystotomy wounds were not unusual. In at least 2 patients there developed fecal fistulas, and in 4 communications developed between the bladder and the vagina. Radiation proctitis, varying degrees of incontinence, late radiation ulcerations of the skin and chronic edema of the genitalia, while not common, were by no means infrequent. Diversion of the urinary stream for symptomatic relief seemed to be performed more commonly as the series increased, but even so 3 patients had cystectomies performed to prevent exsanguination after radiation therapy and urinary diversion had been accomplished. Of course, metastases and local extension of cancer were commonly seen. These considerations should not imply that all this morbidity resulted from the radiation rather than from the disease, but certainly an extensive morbidity was not avoided by radiation, and probably some was added.

A problem which frequently arose was the difficulty of determining whether tumor still existed beneath the inflammation and slough. This is also one of the difficulties encountered in compiling the statistics.

Undoubtedly some of the patients died from the treatment rather than from the disease, as some mortality, however slight, results from almost any form of treatment. How frequently this untoward situation occurred is difficult to say, but some known facts do throw a light on the matter. Of 53 autopsies, including a few apparently accurate reports on cases from other institutions, no metastases were found in 23; 27 did have metastases, while in 3 no statement in this regard appeared in the record. In other words nearly half of the fatal and completely studied cases in these institutions, which are not primarily for terminal care, did not have metastases sufficiently developed to be recognized at autopsy. At any rate, nearly one half of these dead patients died not of carcinomatosis but primarily of sepsis and obstruction of the upper part of the urinary tract, except for the few dying of such relatively unconnected causes as embolism and coronary thrombosis. It seems apparent, therefore, that the rate of survival would have been definitely improved if the upper portion of the urinary tract had been protected from obstruction and infection. In fact, this protection was lacking to such an extent that a significant number of patients died from this lack, some of whom might otherwise have been cured. If a method could be devised for protecting the kidneys, more cures and certainly longer survivals could be accomplished, whether the treatment of the neoplasm was by radiation therapy or by surgical intervention. Penicillin and sulfonamide drugs will be valuable aids but hardly the main solution to the problem, as mechanical obstructions and sloughing neoplastic tissue are the natural prime causes of infection in this disease, to which the trauma of radiation is so often added.

Hospital mortality after the implantation of radon seeds by cystotomy was approximately 5 per cent, which indicates that only a small portion of the poor results can be attributed to the surgical procedures involved, especially as one remembers that death after operative intervention in a patient with cancer does not by any means indicate that death was due directly to the surgical maneuvers. Since only 15 to 20 per cent of the patients survived five years and only 6 per cent were cured in five years, the average survival time for the radiation-treated cases should be expected to be low. As has already been pointed out from the literature, the average survival, apparently from the time of diagnosis, of untreated patients was nearly nineteen months. The life expectancy for the general population of the same age was approximately fifteen years. With 287 patients (some more recent than 1938) having a complete follow-up of three years or more, death before that time being considered complete also, the average survival was 27.1 months from the time of diagnosis at Memorial Hospital. On the same basis the first 29 patients at the New York Hospital seen after 1932 survived an average of twenty-two months. It seems, therefore, that radiation treatment increased the survival of this group as a whole about six months beyond that of untreated cases but still leaves the group about thirteen years behind the average expectancy of the general population. Occasional cures raised the average, and no doubt less specific measures than radiation itself, such as chemotherapy, played an important role. In brief, it is most difficult to show that radiation therapy significantly benefited the group as a whole from the point of view of average survival.

Perhaps a high percentage of extremely malignant tumors has hidden good results obtained by radiation in the numerically smaller group of tumors of lower grades. Accordingly the composition of a group of 377 roughly consecutive and unselected tumors, including for the moment only papillomas, at the Memorial Hospital from 1932 to 1941 was determined on the basis of the histologic grade of cancer; 132, or 32.2 per cent, were diagnosed benign; 29, or 7.6 per cent, grade 1 cancer; 85, or 22.2 per cent, grade 2; 117, or 31 per cent, grade 3, and 24, or 6.3 per cent, grade 4. Of the 255 histologic cancers of this group, 11.4 per cent were grade 1, 33.3 per cent grade 2, 45.8 per cent grade 3 and 9.4 per cent grade 4. It can be seen that nearly half of the cancers were of grade 3, which, if grading is significant, should have a direct bearing on results and in an unfavorable direction. However, the grade 4 lesions were fortunately few, so that the group of grade 1 and 2 lesions is nearly as large as that of grade 3 cancers. Thus, there is not an overwhelming preponderance of decidedly malignant tumors.

The records of 107 unselected and roughly consecutive cases at the Memorial Hospital, in which the disease was originally diagnosed three or more years previously as grade 1 or 2 cancer, showed the average survival to be 35.1 months, with only 43 patients, or 40.2 per cent, known to survive three years or more. On the same basis 132 patients with grade 3 or 4 lesions survived an average of 21.1 months, with only 15.1 per cent known to survive three years. It can be seen that the composition of the group as to grade of cancer can make a difference in the results for the whole series, but considering that less than half of the patients with low grade lesions survived even the relatively short time of three years, the results obtained by radiation are poor regardless of the histologic composition of the group as a whole.

The classification of tumors of the bladder by histologic grading alone has severe weaknesses. In the present study it has been used for two reasons. First, this is the one characteristic of the tumor which was most constantly present and specifically stated in the records. Second, this quality of the tumor represents the opinion and knowledge of an independent, nonurological observer, who could reproduce the diagnosis on review of the sections as unknowns and whose grading does have a general correlation with the results obtained in these cases.

During this investigation some outstandingly good cases were discovered. Although every record on vesical tumor was not consulted, over 500 were examined. Nine cases of survival for ten years were set aside for further study. Two lesions were simple papillomas; 1 was diagnosed as papillary cancer but was not graded; 3 were grade 1; 1 was grade 2, 1 was probably grade 3, and only 1 was definitely grade 3. Only 2 of these lesions could be classified as anything but small, these 2 being estimated at 4 cm. and 2 cm. in diameter, respectively. Apparently, radiation therapy was responsible for the long survivals in these cases, even though they were rarities.

In summary, there are no five year cures of untreated cancer of the bladder, but approximately 10 per cent of patients may survive five years. On the other hand, 6 per cent of the radiation-treated patients were cured at five years, and 17.3 per cent survived five years. Approximately 90 per cent of patients with untreated cancer of the bladder die within five years, whereas 80 per cent of the radiation-treated patients were known to be dead in five years. Morbidity in both the treated and untreated series was decidedly high. The average survival without treatment was 18.8 months, while the average survival of the group receiving radiation therapy was 24.5 months, compared to a life expectancy in the general population at the same age of approximately fifteen years. All the untreated patients must have died with cancer, although not necessarily of carcinomatosis. In 43 per cent of the autopsies on the radiation-treated patients, metastases were not sufficiently developed to be discovered, indicating that these patients did not die of carcinomatosis. Those with grade 1 and 2 malignant lesions survived, on the average, better than did those with grade 3 and 4 cancer in the radiation series. However, patients with cancer of grades 1 and 2 survived poorly, as indicated by the fact that less than half were known to have survived three years. A small number of ten year survivals, which were apparently obtained by radiation, seems to indicate that it is possible for radiation therapy to cure cancer of the bladder, even though such results are uncommon. Perhaps the very nature of the disease will not permit significant improvement with any armamentarium now available, but these results are so poor even after fairly extensive trial that it seems justifiable to attempt therapy by a different method. If the new method should prove a total failure, the loss to the whole group of patients with cancer of the bladder would be hardly extreme.

The surgical treatment of vesical urinary tumors varies from such relatively simple procedures as cystoscopic fulguration to such extensive measures as transplantation of the ureters and total cystectomy. Few internal cancers are cured by simple local destruction of tissue, and experience with cancer of the bladder does not indicate a major exception. Although I was once of the impression that several small malignant neoplasms had been cured by fulguration, cystoscopically or via cystotomy, critical reexamination of the cases revealed that most of the lesions were histologically simple papillomas which could not be included in the cancer classification. The most optimistic conclusion from this reexamination was that infrequently a small and superficial, usually low grade, tumor had been apparently successfully treated by fulguration alone. But how to select such a case was obviously difficult, as evidenced by many failures in the treatment of seemingly perfect cases and, most infrequently, a good result in a seemingly poorly chosen case. As previously mentioned, the results of fulguration of benign papillomas were not as satisfactory as anticipated, though better than with cancers.

The next more extensive surgical procedure after simple fulguration is resection of the bladder, which has been done in 33 instances. Three deaths occurred in the hospital after operation: 1 due to a cerebrovascular accident, 1 to clinical embolism and 1 to sepsis and carcinomatosis. The longest follow-up is fifty-two months, and many cases are relatively recent. Twelve of the 33 are known now to be dead. The average survival of 30, 3 having been lost after discharge, is 19.9 months, even though the follow-up period is less than twelve months in 14 cases and less than twenty-four months in 17. It will be recalled that patients with untreated vesical cancers apparently survived 18.8 months and the radiation group survived 24.5 months, in a more complete follow-up than is at present possible with this group of resection cases. Three patients with resection of the bladder have subsequently had total cystectomy performed, and 1 other has had a bilateral ureterointestinal transplantation. Eleven of the patients were known to have a recurrence or persistence of the cancer in the bladder. The impression is unavoidable that the lesions which were attacked were too large, and that too little margin was obtained. Reimplantation of the ureter to obtain adequate margin seems entirely justifiable,[3] but if this is done to remove the actual site of the tumor it appears unlikely that sufficient margin will be often obtained. A margin of 3 and preferably 4 cm. of normal-appearing bladder with the underlying perivesical fat would seem to be the minimal extent for a really hopeful resection. Naturally, in bladders with a tendency to multiple origination of neoplasm there would be a high recurrence rate. A rigid comparison cannot be made between the resection and radiation cases, as the resection cases are necessarily selected whereas the radiation cases in general were nearly unselected. On the other hand, it is evident that a small number of carefully selected cases of vesical cancer can be greatly benefited and possibly cured by resection, particularly if the surgeon's understandable desire to save the function of the bladder and avoid more immediately hazardous procedures does not weigh too heavily in the decision.

After partial resection of the bladder, total excision of the organ is the next more extensive step, but this necessitates a preliminary attack on that major urologic problem of the permanent diversion of the urinary stream. Bilateral nephrostomies are difficult to care for and, although urgently required at times, they carry considerable morbidity. This procedure has been used only in dire necessity.

Transplantation of the ureters to the skin is a relatively simple procedure, and relatively few patients die of the operation itself. Nearly all the postoperative deaths can be attributed to the patient's extremely poor preoperative condition. Morbidity from stricture and the formation of abscesses has been common. In occasional patients there have developed calculi. Indwelling catheters were used as a rule, but patients who can and will wear cups without catheters possibly have fewer complications later. At best, however, the patient must wear a cumbersome and untidy apparatus, requiring at least a moderate amount of care. At first, my cystectomy patients had cutaneous transplantations because it was considered that cystectomy was hazardous enough without adding the reported great risk of ureterointestinal transplantation. Subsequent experience proved that the immediate risk of ureterointestinal transplantation was not so great as anticipated, and certainly those patients with good bowel implants have been much more comfortable and clean than those wearing apparatus.

7, 8, 9. Carcinomatosis	
10, 11. Embolism	
12. Operation for perineal carcinoma	
Still alive	61
Longest survival	56 mos.

The early results of ureterointestinal anastomosis in the first 39 cases have been reported in some detail.[4] This series is now increased to 93 patients without appreciable variation from that report. The intraperitoneal Coffey 1 method was used exclusively, and the majority of patients had both ureters transplanted at the same operation. All but 8 operations were performed for the treatment, either curative or palliative, of cancer. The oldest patient was 82 and 6 were in their seventies. Twelve of the 93 patients died in the hospital between the time of operation and the time of discharge. Leakage at the site of anastomosis with resulting peritonitis caused the death of 2 patients. One patient died of small intestinal obstruction due to adhesions in the operative area. These 3 postoperative deaths are the only ones due to complications at the operative site or in the urinary or gastrointestinal tracts. Of the remaining 9 postoperative deaths, 3 patients died of congestive cardiac failure, 2 of embolism, 3 of carcinomatosis and 1 of the effects of a radical operation on a recurrent urethral carcinoma. Thirty-two of these patients, including the 12 just mentioned, are known now to be dead. Sixty-one have survived from one to fifty-six months. Temporary (two to six weeks) nephrostomy was performed on 3 patients postoperatively, but in all 3 instances prompt healing occurred on removal of the tubes, with no further diversion of the urine becoming necessary. One other patient is carrying nephrostomy tubes during her convalescence from cystectomy, but this case is so recent that the outcome cannot be accurately gaged. One patient subsequently required a nephrectomy, but he lived nearly two years with carcinomatosis after the removal of the kidney. One patient has had one ureter successfully implanted into the bowel a second time. Three patients have had one or both ureters transplanted from the bowel to the skin because of poor renal function. No doubt the transfer of the ureters from the bowel to the skin will become a necessity again as the series becomes larger, and perhaps in this series as time passes. However, the present pyelographic and blood chemical evidence does not suggest that the percentage incidence of diversion subsequent to ureterointestinal transplantation will materially increase. It should be pointed out that the possibility of transferring the ureters from the bowel to the skin is not entirely disadvantageous, since valuable although partial rectification of one type of failure after bowel implantation may be thus accomplished. Briefly, of the 81 patients discharged from the hospital, 1 has had a subsequent nephrectomy, 1 has subsequently had a second implantation of one ureter into the bowel, 3 have had one or both ureters transferred to the skin and 1 recent patient has had bilateral nephrostomies. The majority of the patients had an uncomplicated postoperative course and subsequently manifested no clinical evidence of renal disease. Most patients void every three to four hours in the day and twice at night with excellent control. Obviously these are more nearly normal and comfortable than those with ureterocutaneous anastomoses. Both transplant groups are too recent to allow an accurate estimation of comparative longevity,[5] especially as the vast majority of late deaths in both groups have been due to cancer rather than renal failure. Only 1 patient with ureterointestinal transplants appears to have died of renal failure thus far. This situation shows a significant difference from the radiation-treated group, in which a fairly high percentage died not of carcinomatosis but of urinary obstruction and infection. Paradoxically, the improvement consists in a higher percentage dying of cancer!

Table 6.—*Data on Seventy-Two Total Cystectomies for Neoplasm (Two for Recurrent Papillomatosis)*

Postoperative deaths	2
1. Paralysis from metastasis	
2 Pulmonary collapse	
Still alive	48
Longest survivals:	
Grade 3	68 mos
Adenocarcinoma	66 mos.
Grade 3	60 mos
Lowest possible number of 5 year successful results	3

Total cystectomy, like the other operations, has been performed both for palliation and cure. Seventy-seven such procedures have been carried out, but only 72 were done for neoplastic disease. Two of the 72 patients were operated on for multiple recurrences of histologically benign papillomas. The remaining 70 operations were performed for histologically-proved cancer. Two postoperative deaths occurred: 1 due to pulmonary collapse immediately after operative intervention on a patient with chronic bronchitis and 1 due to paralysis resulting from the collapse of a cervical vertebra due to metastases. Thus in total cystectomy 2 of the 72 patients with tumor and 2 of the 70 with cancer died. The longest survivals have been sixty-eight, sixty-six and sixty months, all by patients without evidence of cancer and still living. The original slides of these 3 patients have been reviewed; 2 were found to indicate grade 3 carcinoma, and 1 was an obviously malignant adenocarcinoma. Twenty-eight of the 70 cancer patients have survived a year or more, and 9 over two years. As far as is known 48 of these 70 patients are living and 22 are dead. Six of the 22 dead apparently died without cancer (with cardiac disease and so on), although this figure cannot be considered highly accurate. In spite of the fact that most patients were recently treated (45 of the 48 living patients were operated on less than five years ago), the immediate death at this time of all the patients having undergone total cystectomy would result in a five year successful result rate of 4.3 per cent. This, then, is the smallest possible rate of success for this group and, especially in consideration of the other factors previously mentioned, compares well with the 0 per cent obtained in untreated cases and the 6 per cent obtained by radiation methods.

My colleagues and I hope that we have improved our methods. In the beginning, cystectomies were done by the suprapubic route only, but in at least 1 instance there was a recurrence in a small bit of prostate which had been left. We now prefer perineoabdominal cystectomy, believing that we feel more certain of obtaining adequate margin by this procedure and that dependent drainage is a considerable asset in the postoperative course of the patient. However, the Belt approach to the prostate was used by one operator, who severely damaged 1 anal sphincter and weakened 2 others, so that these patients must wear pads to prevent urinary soiling which was not present before the cystectomy. None of the patients without the Belt approach has had poor anal control of urine and feces, so that we strongly favor the classic Young perineal approach with the exception that the dissection is purposely carried quite anteriorly, since injury to the external urethral sphincter in these cases is of no consequence and by so doing the anal sphincter is undisturbed. The perineal approach has not thus far led to a perforation of the rectum, while 1 such accident did occur in a difficult suprapubic prostatocystectomy. This preoperatively heavily-radiated, fulgurated and resected patient died four years after cystectomy without evidence of cancer, but at times he thought gas, though not feces, came out of a tiny sinus at the bottom of the deeply-depressed, heavy suprapubic scarring. In 3 instances the entire cystectomy was successfully performed via the vagina. At least 11 operations were performed on a purely palliative basis or as a heroic measure. The average survival of these 11 patients was 15.2 months, with 3 living

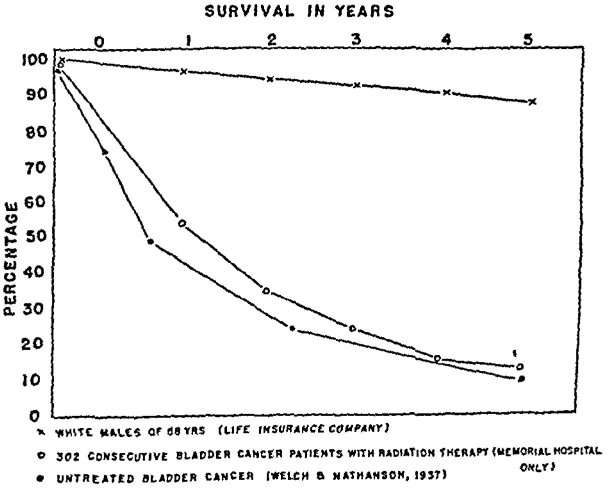

Chart 2—Comparison of survival rates.

---

5. Stevens, A. R.: Longevity Following Uretero Intestinal Anastomosis, J. Urol **46:** 57-66, 1941.

over three years and 1 living four years. Three of the 11 are still alive. Three times cystectomy seemed the only method to prevent exsanguination. The symptomatic relief obtained from cystectomy is impossible to gage closely, but certainly it was impressive in many cases. The relief from urinary diversion alone was often great.

Unfortunately a really accurate comparison of the various groups of patients here reported is impossible. In a radiation series all but moribund patients may be treated, but in a surgical series the local status in the genitourinary tract as well as the general condition of the patient makes some selection necessary even in palliative cases. However, we have been agreeably surprised at what some of these patients can stand surgically. For instance, 1 of these patients had a coronary occlusion just after incision, and the operation was deferred for six weeks. At the end of this time a bilateral ureterointestinal transplantation and later a perineoabdominal cystectomy were successfully carried out. In the tabulation of a radiation series, more can be attributed to the natural course of the disease than in a surgical series, in which a poor result following operative intervention will stand out, at least chronologically, to suggest that the surgical procedure itself has been the cause of the unsuccessful outcome, even though this is not actually true. However, the average survival figures suggest that surgery plays a small role in shortening the life expectancy of the whole group of cancer patients—if, indeed, the average is shortened rather than increased. The patients being treated by radiation can within wide limits be radiated almost indefinitely at one portal or another, whereas a failure after urinary diversion and cystectomy leaves little to be done surgically.

It is difficult to obtain series of each general method of treatment which represent the same degree of perfection in each particular method, as well as during the same progress in the associated fields of medicine. The nearest approach to an accurate comparison probably would be the result of a large series of vesical cancer admissions during a time in which radiation was apparently at its best and the personnel enthusiastic, compared to a similar series during a time of high surgical efficiency and enthusiasm. The method of compiling comparable series by a rigid alternation of cases would be valuable but since surgical and radiation technics do not necessarily make parallel or proportional chronologic improvement, one series might receive the best therapy for that type of treatment whereas the other might fall far short of showing the best its method had to offer. Also, the enthusiasm and efficiency of personnel cannot be so clearly estimated and relied on when two methods are being tried simultaneously as they can when a decision has been made to treat the overwhelming majority of patients by one method. It is necessary to be enthusiastic to make such a decision. It is not assured that the present strong tendency toward surgical intervention will produce decidedly better results than those with radiation therapy, but it is most unlikely that the results will be worse. Certainly, results will be better than those obtained without treatment.

This investigation does not indicate that radiation therapy should be totally discarded, if for no other reason than that cures have been obtained by its use. Also some palliation, mainly in late metastatic cases, has accrued. In some instances it probably is advantageous to use both methods of treatment, particularly after the obvious failure of one. This study seems to indicate that basing the main reliance in the treatment of cancer of the bladder on surgical methods will result, at the least, in a small increase in five year successful results, a moderate improvement in average survival and a really significant amount of palliation as compared with the results obtained by radiation methods.

THE SURGICAL TREATMENT OF CARCINOMA OF THE BLADDER

JAMES T. PRIESTLEY, M.D.
Division of Surgery, Mayo Clinic
Rochester, Minn.

One reads and hears many different opinions in regard to the treatment of carcinoma of the bladder. This is due in part to the variety of characteristics which malignant lesions in the bladder may present; hence the numerous problems which are created from the point of view of treatment. More reports of well controlled series of cases in which treatment is by various available methods and the patients are followed for an adequate length of time would help to clarify present opinions. Because of the many therapeutic approaches available, ranging from external irradiation or cystoscopic procedures to more extensive suprapubic operations, one is always confronted with the decision as to how radical the initial form of treatment should be. In reaching this decision it would seem that the chance of ultimate survival should be given equal consideration with the immediate risk of treatment. It should also be kept in mind that the best chance to cure cancer anywhere in the body always is the first chance. The seriousness of a given carcinoma of the bladder, the risk of one form of treatment as compared with another and the ultimate result that may be expected will be variously estimated. These are some of the reasons which make for difference of opinion in regard to indications for treatment.

This discussion is presented not with the misguided impression that it solves all the problems related to the treatment of vesical neoplasm but only for the purpose of recording the experience of one group and expressing a few personal opinions. In general it is my belief that a too conservative opinion exists regarding the treatment of vesical neoplasm. Cancer in other parts of the body is treated by extensive measures, even though the lesion when first discovered is only several centimeters in size. It seems reasonable that similar measures should be employed in treating cancer of the bladder. The use of roentgen therapy will not be discussed, as in my practice this is never the treatment of choice but is utilized only when other methods are impractical of application.

TRANSURETHRAL VERSUS SUPRAPUBIC SURGERY

One of the first decisions that must be made before the institution of treatment for a given patient who has a vesical neoplasm is whether a transurethral or a suprapubic approach is preferable. The small, noninfiltrating, low grade and well differentiated lesions

---

Read in a symposium on "Urinary Vesical Tumors" before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

are best suited to transurethral treatment. As one's experience with transurethral measures grows, somewhat larger lesions may be treated in this manner. The inherent limitations of this approach, however, always will circumscribe what can be accomplished by this method, and it has been the observation of my colleagues and me that even experienced cystoscopists frequently tend to underestimate the extent to which a vesical neoplasm may involve the wall of the bladder. This is due not necessarily to error on the part of the cystoscopist but to the fact that invasion of the vesical wall by carcinoma may occur without visible evidence on the mucosal surface of the bladder. The depth and extent of invasion in the vesical wall can be determined by the cystoscopist only by indirect and somewhat inferential methods. For this reason it seems safer to err on the side of favoring suprapubic exploration in questionable or borderline types of cases rather than transurethral measures, which time may prove to be inadequate. The details of transurethral treatment will not be discussed.

Table 1.—*Malignant Lesions of the Bladder: Suprapubic and Transurethral Procedures, 1940-1945 Inclusive*

Procedure	Operations	% of Total	Hospital Mortality Rate, %
Suprapubic	211	27.3	6.6
Transurethral	562	72.7	1.1
Total	773	100.0	2.6

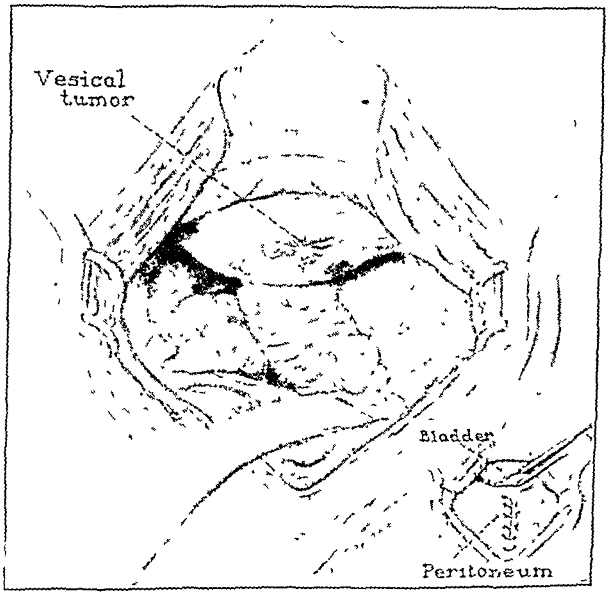
The relative incidence with which transurethral and suprapubic procedures have been employed as the initial form of treatment in one clinic during the past six years is shown in table 1. I am not certain that this represents the desirable distribution. There has been a tendency gradually to use suprapubic procedures more frequently. Obviously the operative mortality rate of suprapubic treatment is higher than that after transurethral measures. It should be kept in mind, however, that in the type of case in which suprapubic operation is used the prognosis is invariably less favorable than in the one in which transurethral measures are used. Thus in the group of cases shown in table 1, of those in which transurethral measures were employed 85.1 per cent of the lesions were grade 1 or 2 (Broders' method) and only 14.9 per cent were grade 3 or 4. In contrast, in those cases in which the suprapubic approach was used only 37 per cent of the lesions were grade 1 or 2 whereas 63 per cent were grade 3 or 4. In deciding on the therapeutic approach, one must always consider not only the immediate mortality rate of a given procedure but also the chance it affords for ultimate survival of the patient.

Of the many details which should be considered in deciding on the most desirable form of treatment for an individual patient who has carcinoma of the bladder, the following might be mentioned: the size, location and grade of the lesion; whether it is pedunculated or infiltrating; whether the lesion is single or multiple; the presence or absence of involvement of one or both ureteral orifices; the status of renal function; the existence of serious renal infection, and the age and general condition of the patient. Obviously all these factors are subject to individual variations of interpretation, a fact which may be responsible for divided opinion in regard to the treatment of choice for an individual patient. The experience and capabilities of the surgeon who treats the patient also must be taken into account. In general, all except the smallest infiltrating lesions are managed best, in my opinion, by the suprapubic approach.

Along the same line of thought, transurethral procedures which, in the mind of the one who employs them, appear to be of questionable adequacy should be discouraged. A temporizing attitude in the treatment of cancer is fundamentally wrong. Fairly frequently one operates suprapubically for recurrent cancer of the bladder, which actually is a persistence of cancer after inadequate transurethral treatment. The chance of ultimate cure under these circumstances is less favorable than if the lesion had been treated originally by suprapubic measures. It is appreciated that not all suprapubic operations for cancer of the bladder will result in complete removal or destruction of the growth. However, in general a better opportunity to accomplish this is afforded by suprapubic than by transurethral procedures.

THE SUPRAPUBIC APPROACH

I am convinced that in any case in which a suprapubic operation is performed for vesical neoplasm intraperitoneal exploration should precede any direct attack on the bladder, as advocated many years ago by Dr. C. H. Mayo. The peritoneum should be opened through a low midline incision, and exploration should include the liver and periaortic and regional lymph nodes as well as the bladder (see the accompanying illustration). Without information obtained by this preliminary exploration, which is comparable to that performed in the treatment of cancer in other parts of the body, one does not know the local extent of the growth or whether regional extension or distant metastasis has occurred. Without this knowledge it is impossible to select the type of surgical procedure best suited to the individual patient and to know whether



Transperitoneal abdominal exploration is performed as a preliminary step in the surgical treatment of vesical neoplasm. The peritoneum is closed prior to direct attack on the lesion.

the procedure performed will offer a chance of cure or merely palliation. It seems to me that the importance of intraperitoneal exploration as a preliminary step to any suprapubic operation for vesical neoplasm has been inadequately stressed. In addition to affording information on the extension of the malignant lesion beyond the bladder, such examination is of distinct help in determining from the size, location in the bladder and local extent of the growth the best surgical procedure for a given lesion. Thus, although one's preoperative opinion may have been that total cystectomy would be necessary to eliminate the growth completely and the patient was prepared preoperatively accordingly, one may discover on preliminary exploration that segmental resection will suffice to accomplish the desired result. The extent of perivesical extension and involvement of the peritoneum over the posterior wall of the bladder can be determined with much greater satisfaction by transperitoneal exploration than by any other method.

After this exploration is concluded the peritoneum is closed, and this line of closure is protected with a large moist pack before any local operation is performed on the bladder. So far as I have been able to determine, the surgical risk is not altered in any way by preliminary intraperitoneal exploration.

METHODS OF SUPRAPUBIC TREATMENT

Many different forms of suprapubic treatment have been devised and employed for the treatment of cancer of the bladder. The three procedures which have been utilized most frequently in my experience have been segmental resection; excision and fulguration, with or without simultaneous implantation of radon,[1] and total cystectomy. Table 2 shows the relative frequency with which these different procedures have been employed during the past six years and the mortality rate associated with each type of operation. During this time the use of segmental resection has remained about the same; however, fulguration with or without the simultaneous implantation of radon has been used less frequently and total cystectomy has been used more frequently in the latter part of the period than in the former.

Segmental Resection.—Segmental resection of the bladder for carcinoma is a highly satisfactory procedure in a selected group of cases. It is best suited for a growth which is well removed from either ureterovesical orifice, which is situated high in the bladder, either in the dome or on one of the walls, and which is within reasonable limits of size. It is employed usually in treating an infiltrative type of growth. A growth situated in the vicinity of a ureteral orifice can be removed by segmental resection and the ureter reimplanted into the bladder; however, my colleagues and I prefer to employ this procedure only in the exceptional case.

Technical procedures involved in performing segmental resection are not difficult, provided the lesion does not extend down to the base of the bladder. One should always excise the lesion completely with what appears to be normal mucosa for a distance of at least 2 cm. on all sides of the growth. At times there may be intramural extension from the growth which is not detectable by the appearance of the surrounding mucosa. The electrosurgical unit may be found helpful in performing segmental resection of the bladder. Needless to say, all local extension and any involved portion of the peritoneum should be removed in one piece with the primary lesion. It has been our practice to close the bladder with two rows of chromic catgut, the inner one of which passes through the mucosa. In almost all cases a straight suprapubic catheter is left in the bladder.

Suprapubic Fulguration With or Without Implantation of Radon.—Suprapubic excision and fulguration seldom is a procedure of choice in treating a vesical neoplasm. This method is reserved for lesions which involve the base of the bladder, including one or both ureteral orifices. In other words, it is employed for a lesion for which total cystectomy usually would be advocated but for some reason is not performed. Such reasons may include poor general condition of the patient, refusal of total cystectomy by the patient or questionable ultimate result which might be obtained, even though the bladder were removed completely.

TABLE 2.—*Malignant Lesions of the Bladder: Incidence and Mortality in Certain Types of Suprapubic Operations, 1940-1945 Inclusive*

Type of Operation	Total Patients	% of Total	Hospital Deaths No.	Hospital Deaths %
Exploration alone *	21	10.0	0	...
Segmental resection	64	30.3	3	4.7
Fulguration with or without implantation of radon	30	14.2	3	10.0
Total cystectomy and bilateral ureterosigmoidostomy †	60	28.4	6	10.0
Total cystectomy with nephrostomy and so forth	5	2.4	0	...
Other suprapubic operations	31	14.7	0	...
Total	211	100.0	12	5.7

* Represents cases in which the lesion was too far advanced to permit any surgical procedure.

† All cases are included in which total cystectomy was either planned or accomplished. Three cases are included in which death followed bilateral ureterosigmoidostomy performed as an initial stage to cystectomy.

After preliminary abdominal exploration, the peritoneum is closed and the bladder is opened through the dome. The location and extent of the growth then are ascertained from the mucosal side of the bladder. By use of the cutting current and loop electrode, all or as much of the growth as possible now is excised. This is an important step prior to fulguration, as by far the bulk of the neoplasm is removed in this manner. In some cases the entire thickness of the vesical wall may be excised in certain regions. Subsequently the entire base and edges of the crater created by the excision are thoroughly fulgurated. One should never stint the extent of the fulguration, regardless of the area of the bladder involved. Here again one should always fulgurate the vesical wall for a distance of several centimeters surrounding the apparent mucosal boundaries of the growth. If one or both ureteral orifices are in an involved area, one always endeavors to identify the ureter as it is cut across by the electric loop and before it is fulgurated. A ureteral catheter of appropriate size then is passed to the corresponding renal pelvis, allowed to remain in place and brought out externally through the urethra or the suprapubic incision. In certain cases neither the ureteral orifice nor the intramural portion of the ureter will be detected, and one or both of these structures will be fulgurated. Through the kindness of nature urine seems to drain from the ureter into the bladder even under these circumstances, although the surgeon never experiences the same satisfaction with his work at the conclusion of the operation. In what percentage of such cases a stricture may develop at the ureterovesical junction in later years, I do not know.

---

[1] Although the distinction is not therapeutically important, in some instances radium instead of radon actually was used.

Decision as to the use of radon in association with electroexcision and fulguration is based on the observations in each individual case. If the surgeon believes that the growth has been dealt with satisfactorily from a local point of view and that no tumor remains which has not been removed or fulgurated, radon is not employed. On the other hand if certain questionable areas remain, insertion of an adequate amount (as nearly as can be determined) of radon is desirable.

Total Cystectomy.—It is my opinion that total cystectomy is a procedure which has not yet been fully appreciated and properly evaluated in the treatment of carcinoma of the bladder. In the past it has carried a high initial mortality rate or has been followed by late results which were not wholly satisfactory. As a result this procedure has not been held in high regard. These facts have been due to many factors, most of which can be eliminated today.

In former years patients were not always prepared properly for the operation. The procedure was used as a last resort in treating extensive, high grade or recurrent lesions, usually without preliminary transperitoneal exploration. Without doubt many of these patients were doomed because of extravesical extension of the lesion which existed but was unappreciated at the time of cystectomy. Urethral transplantation and cystectomy constitute a formidable procedure, which requires a certain amount of experience before it can be performed with a reasonable risk, just as with gastric resection, pneumonectomy or other surgical operations of similar magnitude. With experience, however, a mortality rate comparable to that associated with other major surgical procedures should be attained. The introduction of newer forms of treatment to combat infection has been a material aid in lowering the risk of this as well as other operations. As the operative mortality rate is reduced, as patients are properly selected and as it becomes appreciated that adequate renal function can be maintained for a prolonged period of years after bilateral ureterosigmoidostomy, total cystectomy should assume a position of growing importance in the treatment of vesical neoplasm. In my experience total cystectomy is being employed with increasing frequency. This statement is made despite the fact that many have adopted a defeatist attitude toward this operation. It is true that a certain number of patients experience ureteral obstruction, renal infection and serious interference with renal function after ureterosigmoidostomy. Such developments are considered to be due to technical errors at the time of operation in almost every case, and as one's experience with performing ureterosigmoidostomy increases, these undesirable sequelae to the operation should occur less frequently.

Indications: The indications for total cystectomy are not as clearcut as one would like, but this is equally true of most forms of treatment for vesical neoplasm. Today probably few surgeons would agree completely on any dogmatic list of indications. At the present time, provided the general condition of the patient permits, my colleagues and I consider that the following types of malignant lesions in the bladder justify exploration with the view to total cystectomy: (1) an extensive low grade lesion which involves most of the bladder, (2) a low grade lesion which involves numerous and diversified regions in the bladder, (3) repeatedly recurring low grade lesions, (4) a high grade infiltrating lesion which to the best of one's knowledge can be removed completely by total cystectomy but probably not by any less extensive procedure and (5) any vesical neoplasm which involves portions of the bladder, such as the vesical neck and ureterovesical orifices, which cannot be removed completely without seriously affecting vesical function. Ureteral transplantation and total cystectomy are not performed preferably on the patient who has a recurrent high grade lesion: the ultimate prognosis for any procedure is poor; the patient should have had a more radical form of treatment when his lesion was first detected.

Technic: Total cystectomy obviously presupposes diversion of the flow of urine either to the skin or to the bowel. It is my opinion that transplantation of the ureters to the bowel is far superior, from the patient's point of view, to cutaneous transplantation and, furthermore, that the former can be accomplished in a large majority of cases with reasonable risk and justifiable expectations of satisfactory preservation of renal function over a prolonged period. In former years it was considered unsafe to transplant the dilated ureter into the bowel. It is now known from experience that in the adult, ureters dilated to a diameter of approximately 1 cm. can be transplanted into the bowel with relative safety, provided there is not too much thickening of the ureteral wall. In cases of this type it may be advisable to use an indwelling soft rubber catheter of an appropriate size at the time the anastomosis is established.

Whether extraperitoneal or transperitoneal ureterosigmoidostomy is performed may be simply a matter of the individual surgeon's preference. In former years my colleagues and I used the extraperitoneal approach. We now feel that we can perform the operation transperitoneally with no increased risk. The latter procedure is easier technically and affords superior exposure and alinement of the anastomosis. Satisfactory results can be obtained by an exceedingly simple type of operation, and for many reasons it seems desirable to keep the technical aspects of the procedure as simple as possible.

How many stages should be utilized in accomplishing ureteral transplantation and complete removal of the bladder for carcinoma is a currently controversial subject. In many fields of surgery staged procedures are used much less frequently, and rightly so, than in former years. Previously it was my custom to perform bilateral extraperitoneal ureterosigmoidostomy at the original operation and several weeks later to remove the bladder. During the last few years my colleagues, Dr. Counseller and Dr. Ferris, have been performing the whole operation at one stage with favorable results. Through a low midline transperitoneal incision the ureters are transplanted and the bladder is removed. I have had the opportunity to try this in a limited number of cases during recent months and have been impressed with the desirability of this one stage procedure.

In brief, the following procedure is now employed: The patient is hospitalized for a minimum of four days of preoperative preparation. During this time a nonresidue diet with vitamin supplements is given, and 4 Gm. of succinylsulfathiazole every three hours for six doses, then 2 Gm. four times a day, is administered. The bowel is cleaned with cathartics the first three days. Rectal irrigations are given twice daily until the day before operation. In the evening and morning before operation the rectum is aspirated and paregoric is administered.

Inhalation anesthesia is employed. After exploration through a low midline incision bilateral ureterosigmoidostomy is performed after a simple modified Coffey I technic. A maximum of three or four stitches is used to accomplish the transplantation, including the stitch which leads the ureter into the bowel. Every effort is made to obtain an anastomosis without tension, angulation or compression of the ureter at any point. The ureter extends into the bowel at least 1 cm. The bowel is fixed in the desired position with several interrupted stitches. Catheters are employed only in the exceptional case in which grossly enlarged ureters are encountered. After transplantation of the ureters, the peritoneum is dissected free from the bladder and closed by suture and the bladder is removed. If the patient is male the prostate and seminal vesicles always are removed with the bladder. In addition to ordinary suprapubic drainage, one end of a long Penrose type drain is passed out of the urethra and the other end is brought out of the incision suprapubically. A large rectal tube is inserted and left in place, usually for seven to ten days postoperatively.

Postoperative administration of fluids is started by mouth approximately forty-eight hours after operation, followed by a liquid and then a soft nonresidue diet. A diet of average residue is not given until the rectal tube is removed. Prophylactic chemotherapy is given for a few days after operation. Other postoperative measures are similar to those employed after any operation of similar magnitude.

COMMENT

It is my feeling that in general a too conservative attitude has prevailed regarding the treatment of vesical neoplasm. Small cancers elsewhere in the body uniformly are treated by radical measures. This is true of the breast, stomach, intestine and uterus, and it seems logical to believe that similar measures should be employed in the management of cancer of the bladder. The reported incidence of recurrence after various conservative forms of treatment for the relatively small and low grade lesions, which should offer the best prognosis if properly treated, attests the need for adequate measures at the time the growth first is discovered. This statement is not intended by any means to imply that total cystectomy should be employed in all cases, as this is far from my opinion. It does mean, however, that complete removal or destruction of the tumor should be the primary concern and that the immediate advantages of a conservative method of approach should not weigh too heavily in deciding on the most desirable form of treatment for a given patient.

There still is need for a comprehensive study of end results obtained in the treatment of vesical neoplasm, wherein various forms of treatment are correlated with the many variables which result when cancer develops in the bladder. Thus, results obtained after individual methods of management should be studied in relation with the characteristics of the tumor treated, such as grade, degree of infiltration, size, multiplicity and location in the bladder. Only by more accurate evaluation of results will indications for treatment become more clearcut and better understood. Probably it will be several years before a satisfactory study can be made of ultimate results after total cystectomy performed for vesical neoplasm.

SUMMARY

Many factors must be considered in deciding on the most desirable type of treatment for a patient who has carcinoma of the bladder. These include the size, grade and location of the lesion, the degree of infiltration, whether the lesion is single or multiple, whether the ureterovesical orifice is involved on one or both sides, the status of renal function, the age and general condition of the patient and the risk and prospect of cure afforded by various available procedures. It should be remembered that even the most capable cystoscopist is subject to the inherent limitations of all transurethral procedures in treating a vesical carcinoma through the cystoscope. It is thought that in general the treatment of vesical neoplasm has been too conservative in type. External irradiation is not considered a primary treatment of choice.

The principal suprapubic procedures employed in the eradication of vesical neoplasm are electroexcision and fulguration, with or without the simultaneous implantation of radon, segmental resection (in rare cases local excision) and total cystectomy. Segmental resection seems satisfactory for a limited number of properly situated growths. Total cystectomy is in the process of being reevaluated and it is thought that its field of usefulness is broader than has been appreciated in the past. Bilateral ureterosigmoidostomy, which can be performed in most cases of vesical neoplasm, is considered the desirable form of diversion of the urinary flow in association with total cystectomy.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. JEWETT; MC DONALD, FILIP AND WILLIAMS; MARSHALL AND PRIESTLEY

DR. FRANK HINMAN, San Francisco: It is remarkable that these four papers—all of them excellent—are as much in agreement as they are. The problem of tumors of the bladder is largely one of differential diagnosis and selection of treatment. The problem is changing, however, from what it was a number of years ago. Ten years ago it was estimated that probably 90 per cent of all tumors of the bladder were papillomatous. Of malignant tumors of the bladder 80 per cent are in people over 65 years of age and 90 per cent in those over 50. From the years 1930 to 1940, the number of people over 65 in the United States increased by 35 per cent. The significance of this is that the incidence of cancer of the bladder is increasing. In differential diagnosis one must consider the proper application of four different methods of treatment: (1) fulguration; (2) irradiation; (3) surgical resection of the local growth, and (4) radical cystectomy. The early papillomas and a number of infiltrating papillomas can be cured, but there are types of infiltrating tumors which cannot be cured by diathermy. The differential point to decide in making the examination is what the treatment will be. Will the physician depend on diathermy or at once adopt some radical procedure? Radium or roentgen radiation may be used. Tumors so located as to be resectable can be successfully treated by this method. There are cases, however, in which neither diathermy nor resection can be used, and for them the treatment 's total cystectomy with transplantation of the ureters. The important thing in differential diagnosis is to be able to make this decision early. There are many cases of total cystectomy that are not successful because of the procrastination and delay in subjecting such patients to this radical procedure. If the physican could decide that the only hope for these patients was a total cystectomy and a ureteral transplantation, he probably would perform the operation earlier and save more of these patients than he does. In the fulguration treatment, it is important to have regular periods of reexamination. It has been my custom to have the patient back a month after the first fulguration and then possibly destroy any recurrence. If there is no recurrence they return in two months, then three months, then every three months for a period of two years and then at six month intervals for another two or three years. The patient is usually followed for at least three years after the period of last recurrence. There is no doubt that thorough fulguration and deep diathermy cures many papillomatous tumors. It will not cure the sessile flat infiltrating tumors. These tumors have to be cured by either radium therapy or surgical resection. My experience with irradiation has been like that of the speakers—terribly disappointing. Many of these patients have suffered a year or more with excruciating burns of the bladder. There is not much that can be done to relieve them. Vesical tumors—practically all of them—are radioresistant. The majority of urologists rely on the other three methods—fulguration, wide resection when possible and as a last resort either palliation or radical cystectomy with transplantation of the ureters.

Dr. Oswald S. Lowsley, New York: The scholarly presentation of Dr. Hugh Jewett indicates the results obtained in the clinic, which was always predominantly surgical although other methods were utilized. Dr. Marshall has presented statistics, some of which are from the Memorial Hospital, where emphasis has been placed on radiation but surgical procedures have also been done. Dr. Marshall says that radiation can cure cancer but does so in only a small percentage of cases, and the general results are only a little bit better than those noted in untreated cases as far as life expectancy is concerned. This is a most important observation, coming from the world's greatest center of enthusiasm for radiation. Dr. Jewett has called attention to the four causes of failure in any method of treatment. With those observations I heartily agree, but I feel that sometimes operation, either cystectomy or even transplantation of ureters to the bowel in hopeless cases, is advisable for the relief of pain, because it is the duty of the physicians not only to "heal the sick but to relieve human suffering." The best results in my experience have been obtained by suprapubic thorough resection of vesical tumors, large or small, with a wide cuff of normal bladder wall. One may have to transplant the ureter to another part of the bladder. My first operation of this sort was done in 1918, and this patient is hale and hearty today and so grateful that he presents the research fund with $5,000 annually. This resection should be done regardless of the grade of the tumor if it is accessible and the patient's condition warrants the operation, because I have had several cases of grade 1 tumor in which the patients have come back months later with grade 3 or 4 tumors. Following the removal of any tumor of the bladder it is my custom to utilize the Kirwin treatment, which consists of bathing the operative site with a solution of carbolic acid 50 per cent in glycerin for three minutes, followed by alcohol. This prevents implants most effectively. I heartily agree with Harold McDonald that these patients should be followed, and with regular cystoscopic examination. I believe in fulgurating small papillomatous tumors. I have one patient, an old lady, who comes back to see me once every three months. It is seldom that I do not find a pea-sized tumor to fulgurate. I have fulgurated more than a hundred tumors, but to operate on this woman would be silly because the tumors are small. This is certainly the best thing to do in this particular case. Let me add my voice to those who recommend that all physicians urge their patients to undergo a thorough urologic examination when blood, either microscopic or macroscopic, is discovered in the urine. Painless hematuria should be considered a most serious symptom, to be viewed with alarm until its source is discovered. Only in this way will there ever be an opportunity to cure cancer of the bladder, or of any other organ of the genitourinary tract, by operative intervention.

Dr. Lloyd G. Lewis, Washington, D. C.: Urologists have been extremely conservative in the treatment of cancer by surgical means. Yet one should not rush into a radical procedure such as total cystectomy unless one is sure that the operation is indicated. I recommend endoscopic treatment of grade 1 tumors and approve of total cystectomy for extensive infiltrating tumors without evidence of metastasis. There is, between these two types, a group of tumors, grades 1 and 2, which tend to recur. I have used total cystectomy for multiple recurrent tumors. Dr. Kirwin has used carbolic acid treatment. We have considered adapting radium therapy to meet this problem. The lethal tumor dose must be determined and administered. The dose for cancer of the bladder ranges from 8,000 to 12,000 r. Implantation of radon or radium needles means "hot spots" and inadequate total dosage. Roentgen rays produce extensive damage to skin and bowel. The principle we propose is not new; it is similar to the radium pack. A 25 mg. capsule of radium is placed in the drainage tube of the Foley catheter, and the balloon is inflated to 35 cc. so that the radium lies at the center of the sphere with a radius of 2 cm. At operation, cystostomy is performed and the tumor is resected or fulgurated. Radiation at point source is 100 per cent, at 1 cm. 60 per cent, at 2 cm. approximately 25 per cent and at 3 cm. about 9 per cent. Because 90 per cent of the tumors occur in the prostatic portion of the bladder, irradiation of the tumor-bearing area and the area of recurrence is accomplished. This method is not satisfactory for deeply infiltrating tumors, but it seems ideal for superficial tumors and for prophylactic irradiation to prevent recurrence. We have used this method in 8 cases; the first patient, a boy of 19 with multiple grade 2 tumors filling the bladder, has had no recurrence one year following radiation; 2 female patients with small grade 3 infiltrating tumors have had no recurrence at eight and nine months, respectively. The other cases are too recent for appraisal. Adequate radiation will kill vesical cancer cells; however with adequate dosage there must be radium-induced cystitis, which clears in six or eight months. Radium may contribute to the handling of tumors which are not susceptible to transurethral surgery alone and in which one is doubtful of the necessity for carrying out cystectomy. I believe that a radium balloon catheter with adequate drainage facility can be made so that cystostomy will not be necessary.

Dr. Roger W. Barnes, Los Angeles: I would like to ask Dr. Jewett whether it is possible in his B group of tumors, those which have infiltrated the bladder musculature but have not extended entirely through, to determine the amount of this infiltration by taking one or two biopsy specimens? Isn't it usual that one area of these tumors is infiltrated much more deeply than another area? Tumors of the bladder which had transurethral resection and fulguration alone were compared with those which had a combination of resection and radon implantation. In grade 1 malignancy and papilloma radon seeds were not used. In grade 2 and grade 3 malignancy the length of life of patients who had the combined resection and implantation of radon seeds was a little longer for each grade than that of the group which had resection and fulguration only. In other groups there was an extension of life in the cases in which both the transurethral resection and fulguration and radon were used over those in which there was transurethral resection and fulguration only.

Dr. Gilbert J. Thomas, Beverly Hills, Calif.: The members of the American Urological Association have expended a large sum of money for the maintenance of a registry so that all tumors of the bladder seen by urologists may be graded and studied. This study has been a group project for a great many years I was never satisfied that the conclusions obtained from this study of vesical tumors was accurate and that the treatment applied was adequate Many of the bits of tumors that have been sent in to the laboratory at the Army Medical Museum have not been accurate specimens removed from that portion of the tumor in which urologists are most interested Dr. Jewett has suggested that bits of muscle fibers should be part of every biopsy specimen obtained, as these reveal that the specimen came from the wall of the bladder and not from the top of the tumor The methods suggested by the essayists make possible an accurate microscopic diagnosis of the presence and extent of the condition Dr Jewett has alluded to this method of diagnosis of the character of the tumor Dr Priestley explores the abdomen when a tumor of the bladder is present He searches for and determines the extent of local spread or metastasis Urologists were shunted onto a sidetrack during their treatment of tumors of the urinary bladder with the advent of the transurethral resection Many undiagnosed tumors of the bladder have been resected and fulgurated transurethrally when segmental resection should have been practiced or a complete cystectomy performed More patients should be subjected to early cystectomy, which would follow complete diagnosis and preoperative care which includes the correction of nutritional deficiency, replacement of blood and fluid losses and disinfection of the urinary tract and of the lower bowel, together with the selection of a proper anesthetic or a combination of anesthetics This disease should be attacked as boldly as it is by the rectal or stomach surgeons If the suggestions that have been made today are followed one can make an accurate diagnosis of the condition present and can plan a method of attack aimed at the cure of the patient When a suprapubic exploration is made and reveals the presence of cancer of the bladder, without metastasis, the surgeon should be prepared to do (at this time) a cystectomy or resection or any other surgical treatment the condition requires One has not cured a papillomatous tumor of the bladder which recurs, so I am wondering why there should be a method of grading the degree of malignancy of these tumors Since recurrences occur frequently, why not employ more radical methods of treatment that are aimed at permanent cure?

Dr Hugh J Jewett, Baltimore Dr Barnes has asked how one detects by biopsy the depth of infiltration of a tumor which presumably has invaded the muscularis I didn't mean to imply that one could The biopsy is used, first, to establish the diagnosis in questionable cases and second, to establish the presence or absence of any infiltration One knows from a properly taken biopsy whether infiltration has occurred If the biopsy includes muscle fibers, one knows at once whether the tumor has reached the muscle The most valuable method of determining preoperatively the depth of infiltration is the bimanual examination I don't wish to suggest at this time the most appropriate treatment for tumors in each of the three stages of infiltration What I do mean to say however, is that there is a considerable difference in the curability of tumors of the urinary bladder, and this depends to a great extent on how deeply they are situated in the wall of the bladder By learning to distinguish between superficially and deeply infiltrating tumors the urologist will know at the end of a period of time which treatment has been best for those particular tumors

Dr Harold P McDonald, Atlanta, Ga As has been pointed out so ably, it is admittedly difficult at times to determine whether or not open transurethral surgical methods should be applied in the treatment of tumors of the bladder When this has been determined it is important, as Dr Thomas mentioned, to be sure that the procedure is thoroughly carried out In removing the tumor by transurethral means it is important to remove the tumor down to its base and at least half through the muscularis of the bladder It is often found that the base of the tumor is malignant whereas the outer portion is not Dr Lewis's suggestion regarding the use of a bag in the administration of radium might in my opinion be helpful in lessening recurrences

THE CUTANEOUS LESIONS IN ACUTE MENINGOCOCCEMIA

A Clinical and Pathologic Study

WILLIAM R HILL, M D
and
THOMAS D KINNEY, M D
Boston

The presence of a cutaneous rash has always been recognized as one of the earliest and most reliable clinical signs in meningococcemia, a fact that has led clinicians in the past to employ such titles as malignant purpuric fever, petechial fever, black fever and spotted fever for these infections. The purpose of this paper is to discuss the cutaneous manifestations of meningococcic infection and to comment on their pathogenesis in relation to the histologic observations in specimens of skin of persons who have had meningococcemia. This study is based on 25 cases taken from the autopsy files of the Peter Bent Brigham, Boston Children's and Boston City hospitals, in which the patients exhibited lesions of the skin during the course of the disease and died as the result of acute meningococcic infection

HISTORY

The first epidemic of meningococcemia reported in North America occurred in Medfield, Mass[1] in 1806, eighty-one years prior to Weichselbaum's discovery of the causative organism, Neisseria intracellularis In 1894 Voeleker[2] described a case of acute fulminating meningococcemia in a patient who presented purpuric cutaneous lesions and at autopsy was found to have bilateral adrenal hemorrhages—the so-called Waterhouse-Friderichsen syndrome (epidemic cerebrospinal meningitis) In 1901 E. Graham Little[3] collected a group of similar cases and identified them as a distinct clinical entity. His report preceded Waterhouse's[4] by ten years and Friderichsen's[5] by seventeen In 1898 Gwyn[6] proved the existence of meningococcemia by recovering the meningococcus through culture of the blood of a patient. In 1906 Andrews[7] supported Gwyn's observations by demonstrating this organism in smears of the peripheral blood of a patient with acute meningococcemia In 1916 Netter and Salanier[8] noted the presence of meningococci in a smear obtained by abrading the purpuric lesions of the skin In the same year Benda[9] and also Pick[10] reported finding meningococci in specimens of skin removed for histologic study

from patients who had died of meningococcemia. Also in 1916, von Drigalski[11] found meningococci in smears of fluid obtained from herpetic vesicles in patients with this disease. One year later Netter, Salanier and Blanchier[12] successfully cultured the meningococcus from material obtained by incising purpuric lesions. In 1931 McLean and Caffey[13] cultured meningococci from bullae that had been raised over purpuric areas by gentle friction.

CLINICAL DATA

Herrick[14] defined three chronologic stages of invasion by meningococci. He believed that after primary localization in the nasopharynx the meningococcus entered the blood stream and gave rise to meningococcemia. This stage of bacteremia, similar to the spirochetemia of early syphilis, is common to all types of meningeal infections. Concomitantly with the stage of bacteremia, or at various intervals thereafter, the meningococci metastasized to the skin, eyes, joints, heart, adrenals or meninges and produced various clinical syndromes.

The number of cases of meningococcic infection exhibiting cutaneous lesions cannot be determined with accuracy, since many of the lesions are asymptomatic, inconspicuous and fleeting in character and are easily overlooked. In Meyer's[15] series of sporadic cases with acute illness, 61 per cent exhibited a cutaneous eruption. In similar groups of patients, Smithburn[16] and his co-workers noted lesions of the skin in 68 per cent and Strong[17] in 82 per cent. Daniels, Solomon, and Jaquette[18] described cutaneous lesions in all the cases that came under their observation during an epidemic. The greater incidence of rashes noted during epidemics is probably due to an increased consciousness of the problems at that time.

The onset and course of the disease in the present series of cases varied widely. The most frequent prodromal symptoms were pharyngitis, laryngitis and conjunctivitis, followed by fever, chills, headache and arthralgia. However, the disease may be ushered in by convulsions or the patient may manifest symptoms of shock.

Irrespective of the type of onset, the most constant sign was the appearance of lesions of the skin. The cutaneous patterns were similar to those described by other authors and included erythematous macules, papules, nodules, vesicles and petechial and purpuric lesions. In the majority of cases a combination of lesions was usually found, since most patients exhibited more than one type of lesion during the course of the disease. These lesions varied in size, shape, number and location. The earliest lesions were ill defined erythematous macules ranging in size from a few millimeters to 10 mm. or more, and some simulated the rose spots of typhoid fever. These were situated over the lower extremities and trunk. Papules, some of which had a central punctum or linear hemorrhage, did not fade on pressure and resembled flea bites, were also observed. In some cases erythema nodosum-like lesions appeared on the lower extremities and were indistinguishable from the type encountered in other diseases.

Hemorrhagic lesions, both petechial and purpuric, were seen in a majority of these cases. The petechiae measured 8 to 35 mm. in diameter, were irregular in outline, were tender to touch and did not fade on pressure. Many coalesced to form larger ovoid or stellate purpuric lesions, which were light purple to black and ranged in size from 5 or 6 cm. to extravasations covering an entire segment of the body. Infrequently the purpuric lesions were surmounted by vesicles and pustules. In none of the present cases was purpura found alone, but in every case in which it occurred it was associated with petechiae.

The course and extent of the eruption were as variable as the lesions themselves. Usually the cutaneous eruption was most prominent on the extremities, but regions of the body subjected to pressure, such as the shoulder, elbows and pelvis, and the region over the deltoid areas subjected to friction were also frequent sites. Petechiae favor the joints, particularly the small joints of the hands, wrists, and ankles, and purpura the extremities and back. The face, palms and soles were only occasionally involved. The lesions usually became generalized, although in a few cases the initial lesions remained localized. Often it was possible to trace the evolution of the eruption, beginning with erythematous maculopapules and progressing to the more commonly observed petechial and purpuric lesions. In 8 of 25 cases a maculopapular rash preceded the petechial lesions.

The lesions usually appeared within twelve to thirty-six hours after the onset of the disease, but in a few cases they were fully developed within a few hours. The course of the eruption was influenced by the type of lesion, the type of therapy and the severity of the infection. The maculopapular lesions may fade in a few days, irrespective of therapy, and usually do so twelve to twenty-four hours after the use of penicillin or sulfonamide compounds. These drugs do not appear to influence the course of the hemorrhagic element of this disease. Petechial and purpuric lesions, which involute slowly over periods of days to weeks in patients who survive, leave a residual light brown pigmentation.

Attention should be called to necrosis and sloughing of purpuric lesions and gangrene of the extremities, which occurred in 2 patients who recovered from acute meningococcemia. In the first of these, irregular bluish black eschars formed over the site of a severe purpuric lesion on the lower extremity. In the second, necrosis of the skin of the toes and later of the entire toes occurred, so that amputation was necessary. Healing of these lesions was extremely slow, the patients requiring months of hospitalization.

The meningococci were typed in 13 of the 25 cases studied. N. intracellularis of type I strain was found in 12 cases and type II in 1 case. Osborne, Arnone and Lythcott[19] stated that pathogenic strains are types I, II and IIa. Korns[20] was of the belief that most patients with clinical cases of the disease harbor type I organisms and that those of carriers belong to type II, especially when the carriers are not intimately associated with patients with active infections. Branham[21] stated that type I organisms are responsible for most epidemic cases and are identified most frequently in the acute fulminating form of the disease. Type I is the organism most commonly present in the beginning of an epidemic; type II is most prevalent during an epidemic.

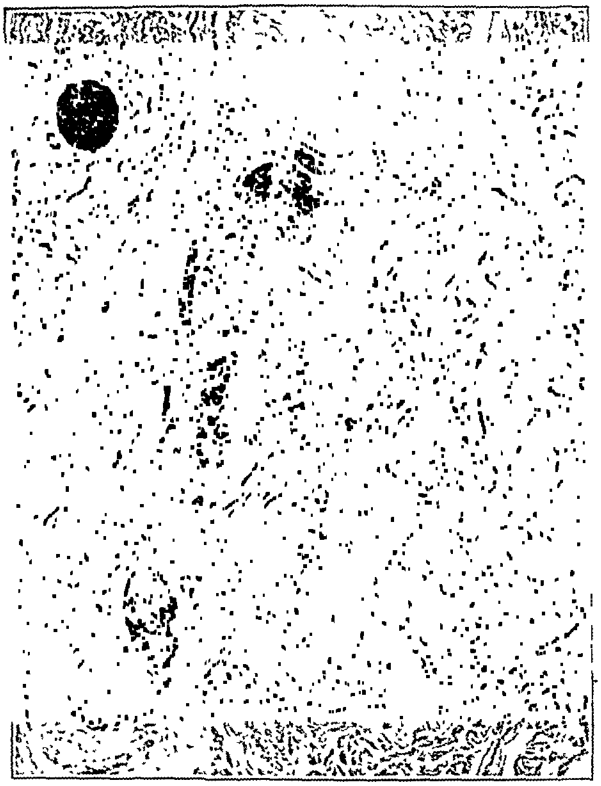

Fig. 1.—The vessels are engorged and packed with red blood cells. In the center of the section diapedesis has resulted in perivascular hemorrhage (low magnification).

It is of interest to note that in 4 cases in which the platelets were observed, they were diminished in 2 cases in which purpuric lesions were pronounced, whereas they were normal in 2 cases in which these lesions were absent. In 1 of the 2 cases in which the platelets were reduced, the clotting times of capillary and venous blood were prolonged, and the clot retention time was increased.

PATHOLOGY OF THE CUTANEOUS LESIONS

The fundamental pathologic lesion in the skin in meningococcemia is diffuse vascular damage. The most constant observation in all our specimens removed for histologic study was diffuse dilatation and engorgement of blood vessels throughout the depth of the cutaneous lesions (fig. 1). This was true irrespective of the type of clinical lesion or of the age of the lesion. This widespread vascular change was not restricted to the skin but was found throughout the serous surfaces and other organs of the body. Study of the smaller blood vessels and capillaries showed endothelial changes. There was decided swelling of endothelial cells, often to such a degree that the continuity of the lining endothelium was broken. These frayed and desquamating lining cells, either singly or in groups, were found partially dilated and protruding into the lumens of the vessels and were frequently seen to be lying free in the lumens. Meningococci could be identified in endothelial cells (figs. 2 and 3) even with routine stains, such as eosin-methylene blue and hematoxylin eosin. These organisms could be demonstrated particularly well with bacterial stains, such as the MacCallum-Goodpasture modification of the Wright stain.

Corroborative evidence of the endothelial damage and subsequent necrosis of the vessel wall was the early appearance of diapedesis of red blood cells, with the formation of small perivascular hemorrhage and larger lakes of red cells. Coincident with this process, or rapidly following it, was the appearance of polymorphonuclear leukocytes lying free in the lumen and infiltrating the areas of endothelial damage. Meningococci could be demonstrated in the cytoplasm of many of these leukocytes. In many vessels, particularly those in which endothelial damage was more pronounced, leukocytes were found throughout the vessels and in the perivascular spaces. In the older lesions many of these were pyknotic or disintegrated. It would appear that these lesions were progressive, in that the bacteria released by the disintegrating phagocytic leukocytes in time attracted more leukocytes. Edema in these sites was well defined, and meningococci were found free in the tissue spaces. In the older lesions a few lymphocytes and débris-containing macrophages were present

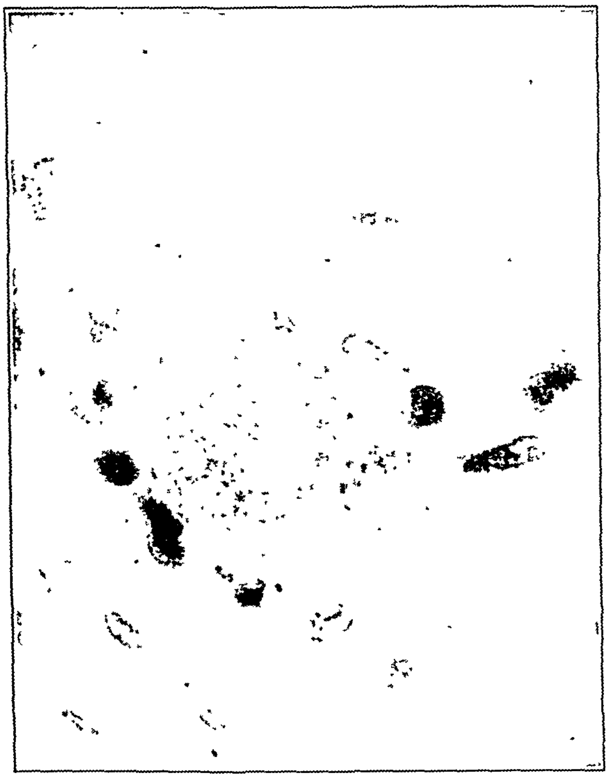

Fig. 2.—Meningococci are visible in the cytoplasm of endothelial cells (oil immersion).

Platelet thrombi were seen in many vessels. These were most prominent in vessels deep in the cutis or in the subcutis, although the superficial capillaries directly beneath the epidermis were involved in a lesser degree. The earliest thrombi were found in vessels in which the endothelium had been damaged and early leukocytic infiltration had taken place. Here fibrin strands, in whose meshes were contained platelets and leukocytes, had attached themselves to the damaged vessel wall and partially occluded the vessel (figs. 4 and 5).

---

[21] Branham, S. E.: Meningococcus Meningitis, J. Pediat. 18:217, 1941.

Elsewhere thrombi completely occluded vessels, and all gradations were often seen in the same sections, suggesting that not all the lesions were equal in age. Organization was demonstrated in a few such thrombi. It should be emphasized that these thrombi were made up for the most part of platelets, red blood cells and fibrin and that they frequently contained meningococci.

Striking changes were present in the sweat glands, which were pale-staining and edematous. The individual cells of the acini were swollen and pale, and their cytoplasm was vacuolated. A few clumped nuclei were often all that remained of completely destroyed sweat glands. These changes were sometimes accompanied by an exudate, which consisted principally of polymorphonuclear leukocytes and contained meningococci. The blood vessels accompanying these glands showed the changes already described, and almost invariably a thrombosed blood vessel could be demonstrated in close proximity to and directly beneath a group of these damaged sweat glands (fig. 6).

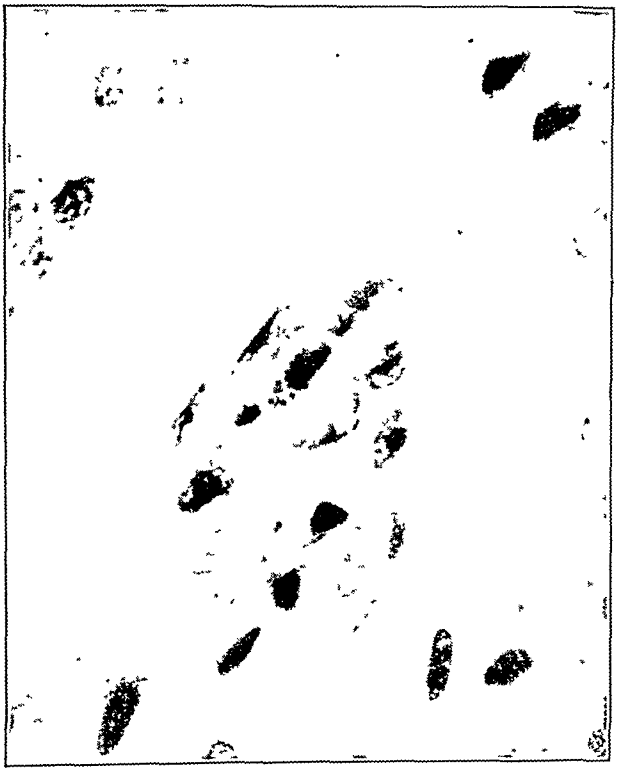

Fig 3 —Meningococci are visible in the cytoplasm of endothelial cells

The erector pili muscles and cutaneous nerves accompanying the arteries and veins were vacuolated, and their interstices were invaded by polymorphonuclear leukocytes. In the subcutaneous fat, focal areas of fibrinous necrosis with numerous phagocytic cells were present.

When vesicles occurred they were subepidermal and unilocular and contained serous and fibrin strands, with little or no inflammatory reaction.

The epidermis was normal in contour and in the arrangement and number of cell layers. Occasionally extensive edema was present in the cutis, and in these sections the collagen fibrils were pale-staining and the rete pegs were obliterated.

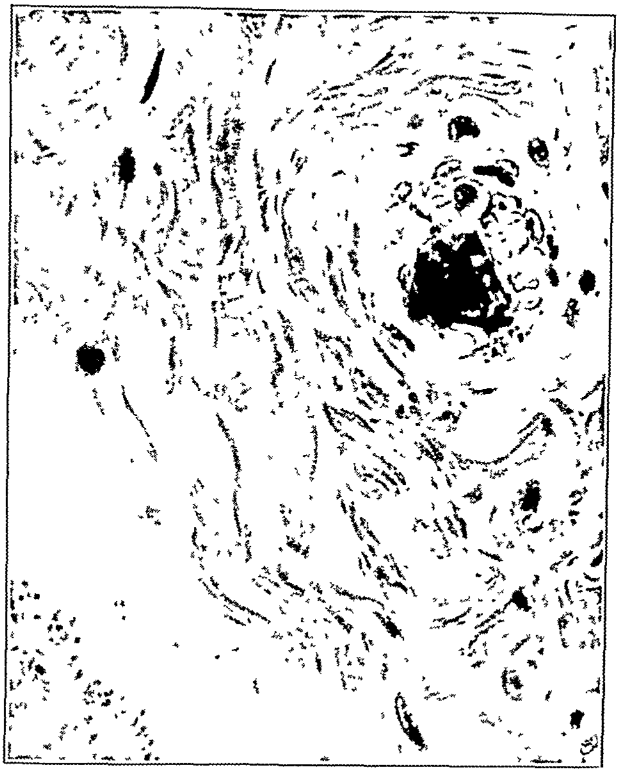

Fig 4 —Thrombus is attached to the endothelial wall of a superficial capillary (high magnification).

COMMENT

From the preceding observations it is evident that the lesions of the skin can all be explained on the basis of vascular damage resulting from the presence of meningococci. The sequence of events in the pathogenesis of the lesions is the localization of the meningococci in the endothelium followed by endothelial damage and inflammation of the vessel walls, with resultant necrosis and thrombosis These changes, by permitting the extravasation of red cells, account for the hemorrhagic cutaneous lesions

Thrombus formation in the cutaneous vessels of patients who have a rash in association with acute meningococcemia has not been sufficiently emphasized. In all cases studied in which the skin manifestations were severe, thrombi were a striking and invariable observation. They were composed largely of platelets that were attracted to the damaged endothelial lining. It appears that in the formation of these thrombi the platelets are drained from the circulating blood more rapidly than they are replaced, so that a thrombocytopenia results. This in turn accentuates the hemorrhagic tendency and aids in the formation of the purpuric lesions. In 2 cases in which purpura was a striking feature, the blood platelets were greatly reduced. Thrombocytopenia is known to occur in many of the severe febrile illnesses, such as septicemia, typhoid fever, typhus fever, scarlet fever and miliary tuberculosis, and it is not unlikely that the fever is also a factor in the reduction of the platelets in this group of cases. In cases not included in this series, thrombocytopenia has been observed both with and without cutaneous manifestations but was always severer in the cases in which such lesions were present. Support for this is given by the fact that in 2 of the foregoing cases in which purpuric lesions did not occur the platelets were stated to be normal. Pratt-Thomas[22] reported moderate reduction in the platelets in 2 cases, and Cosgriff[23] also thought that the purpuric lesions were associated with a thrombocytopenia. However, Pratt-Thomas[22] and Weisberg[24] have reported cases with purpuric lesions in which the platelets were said to be normal in number.

The changes in the sweat glands can be explained on the basis of ischemic necrosis due to interference with the blood supply, since a thrombosed vessel was seen in proximity to the glands in the majority of our sections.

The late complication of gangrene of the skin and extremities is probably also the result of vascular thrombi. In each of the 2 cases which we observed, necrosis of the skin and extremities appeared to progress after the stage of bacteremia had been controlled by sulfadiazine and penicillin therapy. The distribution pattern and progression of these lesions can best be explained on the basis of continued propagation of the thrombi. Physiologic disturbances such as dehydration, loss of vascular tone and blood vessel stasis brought about by the infection would promote the continued propagation of the thrombi already present. These cutaneous complications will undoubtedly become more frequent as more patients survive following the early administration of chemotherapeutic agents, and recognition of the underlying pathologic process will be of aid in planning local therapy.

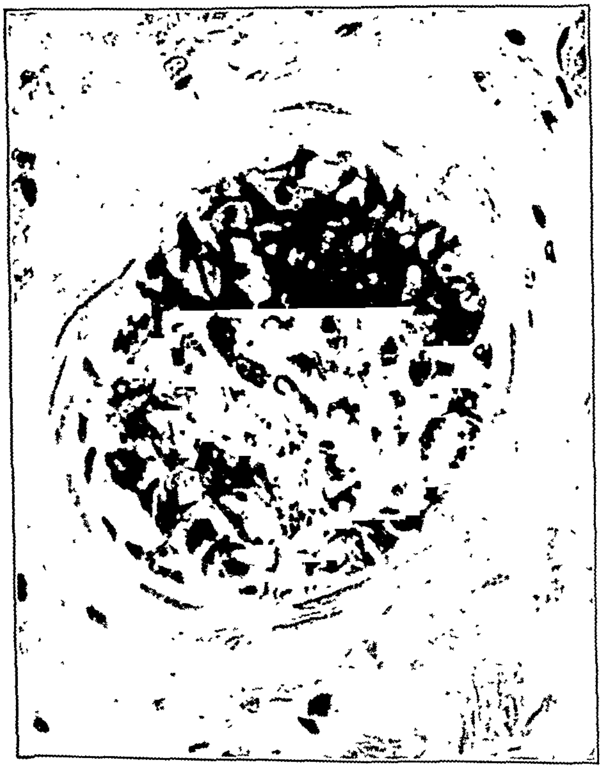

Fig. 5.—Thrombus in a larger vessel composed of platelets and fibrin, has entirely occluded the lumen of the vessel (high magnification).

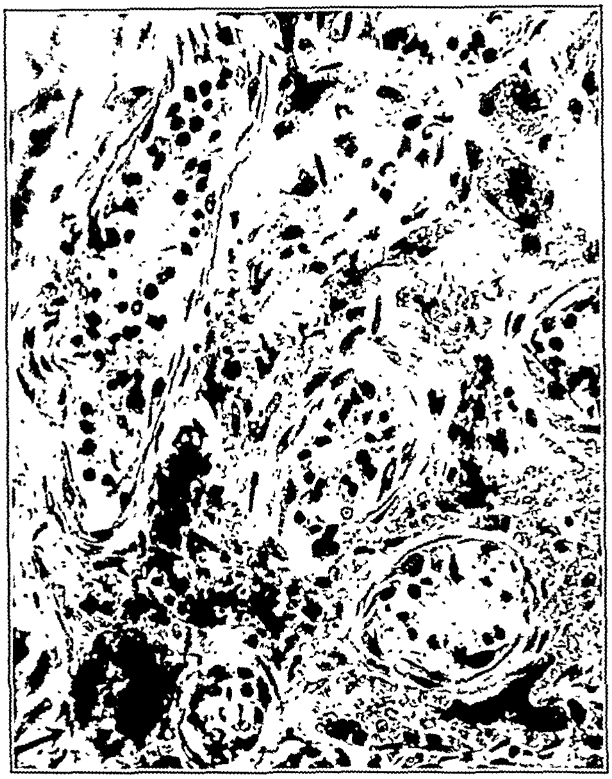

Fig. 6.—Vacuolization of the cytoplasm with pyknosis and clumping of the nuclei has distorted the sweat gland acini. Note thrombosed vessels beneath the group of sweat glands (high magnification).

In the present series vascular lesions were not restricted to the skin. Petechiae and hemorrhagic manifestations were found over the serous surfaces and in the mediastinum, epicardium, endocardium, lungs, liver, kidneys, adrenals, intestines and spleen. The vascular lesions were similar to those in the skin. In other words, the cutaneous lesions are but one manifestation of a generalized disease process.

It has been repeatedly emphasized in the literature that it is possible to demonstrate meningococci in smears of purpuric lesions that have been abraded. This was true in 4 cases in the present series in which this was attempted. Bernhard and Jordan,[25] using this method, found meningococci in 27 of 40 cases, while cultures from these lesions that were read after eighteen hours of incubation were reported to be positive in 35 instances.

In all cases in which sections of skin were available for study in this series it was possible to identify meningococci. In view of the ease with which these organisms were identified and the characteristic histologic picture of the cutaneous lesions, it is surprising that biopsy as a diagnostic adjunct has not gained more widespread recognition. Only two biopsy studies have been reported.[26]

SUMMARY

1. The cutaneous lesions of meningococcemia are the results of vascular damage, which consists of endothelial damage, inflammation of the vessel wall, necrosis and thrombosis. The role of the thrombic vascular lesions is discussed in its relation to clinical cutaneous complications.

2. The histologic picture of the cutaneous lesions in acute meningococcemia and the presence of meningococci are characteristic and specific observations.

ABSTRACT OF DISCUSSION

Dr. Maurice J. Costello, New York: I believe that the cutaneous manifestations are the most striking and important features of meningococcemia. While the eruption usually appears during the first week of the disease, it may appear at any time, may not manifest itself at all or may appear only with each rise of temperature, to fade within twelve to twenty-four hours when the temperature returns to normal. The lesions are polymorphous, beginning as maculopapules, and at times may be of only one type. About a dozen different types of lesions occur. I would like to emphasize several: (1) the erythema nodosum-like lesions such as those occurring in rheumatic fever and in certain eruptions due to drugs; (2) the petechial puncta interspersed with large hemorrhagic blotches, occasionally associated with subconjunctival and mucosal hemorrhages (with this manifestion there may be bilateral adrenal hemorrhage, dyspnea, collapse and death within twenty-four hours); (3) the lesions which resemble "flea bites" containing a central hemorrhagic punctum surrounded by a faint erythematous zone. They are produced by small septic vascular thrombi. These lesions resemble those seen in Rocky Mountain spotted fever, and because of the somewhat similar constitutional symptoms of fever, headache and general irritability this latter disease must be considered in the differential diagnosis of meningococcemia. (4) Dr. Appelbaum, our meningitis expert at Willard Parker Hospital in New York, has called attention to the most distinctive lesion, an irregularly round hemorrhage with a gunmetal-colored center composed of pus cells (*Am. J. M. Sc.* **193**:96 [Jan.] 1937). (5) Another lesion is necrotic, depressed beneath the surface of the skin and bears a superficial resemblance to the papulonecrotic tuberculid in the stage of necrosis. Direct smears from purpuric lesions in meningococcemia offer a quick, easy, accurate method of bacteriologic diagnosis. The variety and frequency of the cutaneous lesions in meningococcemia are ample proof of the ectodermal tropism of the meningococcus.

Dr. Hiram Newton, San Diego, Calif.: In the winter of 1942 at San Diego Naval Hospital there was an epidemic of meningitis in which the cutaneous lesions described by Dr. Hill occurred in a high percentage of cases. A thing that struck me as surprising and caught me off guard was the fact that such lesions can occur and meningococcic septicemia can occur without any meningeal symptoms. I had in my ward 2 such cases which were identical in appearance. There would occur a chill, a high fever and then petechial lesions, which would fade in about three days, to occur again about the time the man was ready to be sent to duty. It fell to Dr. Sam Shelburn, of Dallas, Texas, to suggest a possibility of the infection being a meningococcic septicemia without a concurrent meningitis. Sulfonamide drugs cleared the lesions completely.

Dr. H. J. Templeton, Oakland, Calif.: Dr. Hill's paper recalls to my mind a fine, healthy high school boy who went to a dance one evening, apparently well. The next morning he was slightly ill, and some cutaneous lesions appeared on the body, apparently petechiae from the description of the attending physician. When I saw him in the afternoon, he had massive hemorrhage into practically all of his skin, along with epistaxis, hematemesis, hematuria and melena. In twenty-four hours from the time of onset he was dead from meningitis, and the meningococcus was isolated from the spinal fluid. At that time penicillin or sulfonamide therapy were not available. That shows the ultimate in the degree to which these cutaneous lesions can progress. Since then I have seen, I think, 2 cases of this Waterhouse-Friderichsen syndrome in the Alameda county institutions.

Dr. William R. Hill Jr., Boston: Our paper discusses the acute form of meningococcemia, of which Herrick has said, "No disease so swiftly slays." The case to which Dr. Newton has referred represents the chronic form of meningococcemia which, according to the literature, was observed in epidemic form in the armed services. Such cases are seldom seen in civilian life.

OBSTETRIC ACTIVITIES IN ILLINOIS HOSPITALS DURING 1945

CHARLES NEWBERGER, M.D.
Chicago

In Illinois licensure by the State Department of Public Health is required by statute of all hospitals giving maternity service. To qualify for a maternity license the hospital must comply with a number of regulations established by the Division of Maternal and Child Hygiene in conjunction with medical and hospital advisory groups. Among the requirements for licensure are those dealing with segregation of the obstetric unit, adequate physical arrangement, trained personnel, essential equipment, approved technics and acceptable records. Included in the item of records is the requirement of submission to the Division of Maternal and Child Hygiene of a monthly report which shows the number of mothers and infants cared for, the type of delivery, the operative procedures employed, the incidence and types of complications encountered, the frequency of abortions and ectopic gestations and the number and causes of stillbirths and neonatal and maternal deaths. These reports are given careful study, and annually the data are tabulated for each hospital, for each county and for each group of hospitals with a comparable number of births. Shortly after the end of each calendar year, the department sends each hospital a copy of its individual tabulation together with that of its birth group and the entire state average. Many hospitals have come to use these data as the basis of staff discussion and medical audit. The combined data offer a comprehensive view of the obstetric activities in all the hospitals of the state and present informative and instructive material to those interested in the obstetric specialty.[1]

During 1945, 232 hospitals in Illinois reported 126,309 births. Of these, 62 Chicago hospitals had 57,361 and 170 hospitals in the rest of the state 68,948 births. In view of the fact that Chicago listed 26.7 per cent of all hospitals and 45.4 per cent of the total births, and also because of its rank as an important medical center, tabulations are presented for Chicago, for the state outside of Chicago (designated as "downstate"), and for the total state of Illinois.

Table 1 shows the grouping of the hospitals according to the number of births.

Table 2 shows the number of patients receiving obstetric care and the number of spontaneous and operative deliveries. Included in this table are operative procedures other than those for purpose of the

---

Read before the Section on Obstetrics and Gynecology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

From the Illinois Department of Public Health, Roland R. Cross, M.D., Director; Division of Maternal and Child Hygiene, Henrietta Herbolsheimer, M.D., Chief.

[1] Newberger, C.: Illinois M. J. **87**:136, 1945; Am. J. Obst. & Gynec. **51**:372, 1946.

delivery of the infant, which may have been employed antenatally, intranatally or postnatally.

Although the average incidence for operative deliveries in all Illinois hospitals is 28.5 per cent, in the individual hospitals the ranges are from 3.3 per cent among 213 births to 85.0 per cent among 1,031 births.

The various types of operative deliveries are shown in table 3. As noted in the summaries of previous years, the hospitals in Chicago have a higher operative incidence than the downstate hospitals and a lower percentage of mid and high forceps and of breech extraction and show a decided preference for the low cervical over the classical cesarean section.

The wide range of percentage in identical procedures in individual hospitals is striking. The range in forceps deliveries is from 1.7 per cent in 651 deliveries to 77.2 per cent in 1,021. The cesarean section rate of 3.6 per cent for the state varies in the hospitals from 0.0 per cent in 330 deliveries to 11.3 per cent in 986. For the most part, the high rate for cesarean sections is particularly noted in the smaller hospitals. In one such institution, where only 34 mothers were cared for, there were 26 spontaneous and 8 operative deliveries, all of which were sections, giving this hospital a rate for the abdominal delivery of 23.5 per cent, the highest in the state. Other small hospitals and their section rates are: 4 in 23 deliveries—17.4 per cent; 3 in 28—10.7 per cent; 11 in 117—9.4 per cent; 18 in 176—10.2 per cent; 17 in 187—9.1 per cent, and 36 in 238—15.1 per cent.

TABLE 1.—*Illinois Hospitals Grouped According to Number of Births*

Hospitals	Chicago		Downstate		Total State	
	No. of Hospitals	No. of Births	No. of Hospitals	No. of Births	No. of Hospitals	No. of Births
With less than 50 births..	1	15	19	570	20	585
With 50 to 149 births...	3	266	28	2,837	31	3,103
With 150 to 349 births...	9	2,198	52	12,289	61	14,487
With 350 to 499 births...	6	2,532	18	7,339	24	9,871
With 500 to 999 births...	22	17,149	41	28,084	63	45,233

Total operations.........	19,850	35.0	19,937	29.3	39,787	31.8

Procedures of an operative character for purposes other than the delivery of the infant are shown in table 4. Notable here is the fact that there is more frequent resort to blood transfusion in the Chicago hospitals than in the downstate area.

The significant triad of obstetric hazards, infection, toxemia and hemorrhage, is recorded in 9.8 per cent of all patients. The standard of morbidity is that of the American Committee on Maternal Welfare: a temperature of 100.4 F. (38 C.) or more occurring on any two of the first ten days post partum, exclusive of the first twenty-four hours. Toxemia is considered under three subheads: nonconvulsive patients with edema, hypertension and albuminuria; patients with convulsions, and patients with such other conditions as hyperemesis, or with only a single manifestation of toxic import. The loss of 500 cc. or more of blood is the criterion for determining hemorrhage. In addition to these three inherent maternal factors, there are the dangers of diseases of the cardiovascular, gastrointestinal, glandular and nervous systems. Table 5 gives the reported incidence of all complications.

TABLE 3.—*Operative Procedures for Delivery of the Infant in Illinois Hospitals*

It is noted that the reported state averages for infection, toxemia and hemorrhage are 4.8 per cent, 2.8 per cent and 2.2 per cent respectively. In scrutinizing the individual hospital reports, however, one must conclude that there is evident lack of accuracy in reporting these complications. A hospital report for one month which showed 212 deliveries with an operative incidence of 35.0 per cent and a maternal death from sepsis reported "no" morbidity. A stillbirth or neonatal death may be attributed to maternal eclampsia or placenta previa, and yet no toxemia or hemorrhage is reported. To obtain a more dependable figure on the relative frequency of complications, an analysis was made of the experience of a representative group of hospitals whose reports reflected painstaking care and reliability. In this group with well over 8,000 deliveries, the percentages were: 8.4 for infection, 6.2 for toxemia and 4.6 for hemorrhage.

TABLE 4.—*Operative Procedures in Illinois Hospitals for Purposes Other than the Delivery of the Infant*

In taking stock of the casualties associated with human reproduction due recognition is given to the occurrence of abortions and extrauterine pregnancies. The frequency of these untoward accidents as reported by the hospitals is shown in table 6.

Here, also, as in the matter of reporting complications, there is an unfortunate lapse in dependable information, as evidenced by a record of 4,478 obstetric patients in one hospital with the admission of only 8 ectopic gestations and none of abortion, and another of 1,928 mothers with 7 abortions and no ectopic gestations. Again, reference was made to the group of representative hospitals with more accurate reporting, which revealed that abortion had a ratio to births of 1 to 6, and ectopic pregnancy had a ratio of 1 to 71.

Table 5.—*Incidence and Types of Complications in Illinois Hospitals, 1945*

	Chicago		Downstate		Total State	
	Number	Percentage	Number	Percentage	Number	Percentage

Nonobstetric conditions	104	0.2	171	0.3	275	0.2

In considering the data relative to the infants, information is asked not only of the total number of births, but also the number liveborn, the prematurely born, those who were injured at birth, the stillbirths and the neonatal deaths. The form for reporting this information is now under revision, and it is planned to include questions dealing with congenital malformations, syphilis and diseases of the eye, the skin and the gastrointestinal tract. The basis for determining prematurity is a birth weight under 5½ pounds (2,500 Gm.). Table 7 gives the total number of infants born, the live births, the premature and infants injured at birth.

Table 6.—*Frequency of Abortion and Ectopic Gestation in Illinois Hospitals*

	Chicago		Downstate		Total State	
	Number	Ratio to Births	Number	Ratio to Births	Number	Ratio to Births
Abortions	1,009	1:57	3,089	1:22	4,098	1:31
Ectopic gestations	90	1:637	231	1:298	321	1:393

Table 7.—*Number of Births, Liveborn, Premature and Infants Injured at Birth, in Illinois Hospitals*

	Chicago		Downstate		Total State	
	Number	Percentage	Number	Percentage	Number	Percentage
Total infants born	57,361	100.0	68,948	100.0	126,309	100.0
Liveborn babies	56,177	97.9	67,648	98.1	123,825	98.0
Prematurely born	2,478	4.3	3,613	5.2	6,091	4.8
Injured at birth	192	0.3	163	0.2	355	0.3

It is noted that 98.0 per cent of all infants were liveborn and that 0.3 per cent were injured during birth. The 4.8 per cent for premature births corresponds with figures obtained in previous surveys.

Of prime importance in this yearly analysis is the study of maternal and infant losses. Table 8 shows that the maternal mortality rate was 1.79 per thousand live births, the stillbirth rate was 20.06 per thousand live births and the neonatal death rate was 21.30 per thousand live births.

Worthy of mention is the fact that there were no maternal deaths in 24 Chicago hospitals caring for 21,033 mothers and in 94 downstate hospitals with 26,549 mothers, making a total of 118 hospitals in the state which gave obstetric care to 47,582 mothers. In tragic contrast is the record of one downstate hospital where out of 464 mothers who gave birth to 450 living infants, 8 mothers died, giving this institution a rate of 17.8 per thousand live births, or nearly ten times the average rate for all the hospitals in the state. In the list of hospitals with no maternal loss are 13 of the group which delivered 1,000 or more infants; it includes 1 hospital outside of Chicago with 1,935 patients, and 2 in Chicago with 2,003 and 3,434 mothers, respectively.

Table 8.—*Maternal and Infant Mortality in Illinois Hospitals, 1945*

	Chicago		Downstate		Total State	
	Number	Rate *	Number	Rate *	Number	Rate *
Stillbirths	1,184	21.08	1,300	19.23	2,484	20.06
Neonatal deaths	1,122	19.97	1,515	22.40	2,637	21.30
Maternal deaths	102	1.82	120	1.77	222	1.79

* The rates are per thousand live births

Table 9.—*Causes of Maternal Deaths and Their Frequency in Illinois Hospitals*

International List No	Cause	Chicago		Downstate		Total State	
		Number	Percentage	Number	Percentage	Number	Percentage
140 and 141	Abortion	15	14.7	21	17.5	36	16.2
142	Ectopic	8	7.8	9	7.5	17	7.6
143 and 146	Hemorrhage	18	17.7	17	14.2	35	15.8
144 and 148	Toxemia	21	20.6	28	23.3	49	22.1
145 and 149	Other diseases and acc	13	12.7	17	14.2	30	13.5
147	Infection	21	20.6	22	18.3	43	19.4
150	Unspecified	6	5.9	6	5.0	12	5.4
	Total	102	100.0	120	100.0	222	100.0

The causes of maternal deaths and their frequency, given in table 9, show that toxemia was the primary factor in 22.1 per cent, infection in 19.4 per cent and hemorrhage in 15.8 per cent. If consideration be given to those deaths attributed to abortion and ectopic gestation, where bleeding was of primary concern, hemorrhage would probably be the leading cause of maternal mortality.

Of the 102 counties in the state, 29 have no hospitals licensed for maternity service, 26 counties each have only 1 licensed maternity hospital, 46 have from 2 to 7 hospitals, and Cook County, which includes the city of Chicago, has 76 hospitals for obstetric care. Summaries were prepared of the obstetric activities in each of the 73 counties which have maternity hospital facilities. A visualization of the data relating to fetal and maternal mortality by counties is afforded by the maps of the state shown in figures 1, 2 and 3. As in previous years these figures show that the northern and central areas of the state have lower mortality rates than the counties in the southern section. An interesting fact is shown in figure 3, which points to a total of 29 counties giving care to 10,534 mothers with no maternal mortality.

SUMMARY

A statistical analysis is presented of the care given to 125,016 obstetric patients in the 232 hospitals of Illinois during 1945.

Operative intervention occurred in 31.8 per cent of all mothers. The rate for forceps delivery was 22.7 per cent, and the rate for cesarean section was 3.6 per cent.

Complications were reported in 10.1 per cent of the mothers, with genital infection, preeclampsia and postpartum hemorrhage as the leading conditions. A study of the more carefully prepared hospital records indicates that morbidity was present in 8.4 per cent, toxemia in 6.2 per cent and hemorrhage in 4.6 per cent, a total of 19.2 per cent of the mothers. Transfusion was given in 1.7 per cent.

Abortion and ectopic gestation are reported to bear a ratio to the total births of 1 to 31 and 1 to 393 respectively. Again, through selection of more accurate reporting these ratios were found to be 1 to 6 for abortions, and 1 to 71 for extrauterine pregnancies.

place as a cause of maternal mortality in Illinois hospitals during 1945. Other and unspecified conditions are given as the cause in 42 (18.9 per cent) of the deaths.

It is justifiable to stress again the value of critical examination by the hospital staffs of the information made available to them. Reemphasis may well be made that such studies should lead to improvement in trends of obstetric practice, to stricter observance of sound indications for interference, to lowering unduly high operative rates in some institutions, to less frequent resort to cesarean section in others, to more ready use of blood or plasma for prophylaxis or for treatment and to greater awareness of the importance of complete and accurate medical records. Such procedures should result in a decrease of obstetric complications, earlier recognition and more adequate treatment when abnormalities arise and a further reduction of mortality rates, making childbirth safer for the mother and her infant.

5038 Drexel Boulevard.

ABSTRACT OF DISCUSSION

Dr. Robert D. Mussey, Rochester, Minn.: Dr. Newberger's paper on the obstetric activities in Illinois hospitals during 1945 gives evidence of careful study of the data and thoughtful preparation. The monthly reports from maternity hospitals, from which his data were obtained, are one of the excellent requirements of the Illinois State Department of Public Health for licensure of all hospitals giving maternity service. The author points out that the records of certain hospitals appear to be more reliable than those of others. For example, the statewide incidence of puerperal infection, toxemia and hemorrhage was 4.8, 2.8 and 2.3 per cent of live births respectively. This incidence is amazingly low when it is compared with 8.4 per cent for infection, 6.2 per cent for toxemia and 4.6 per cent for hemorrhage, which are the figures from "a representative group of hospitals in Illinois whose reports reflected painstaking care and reliability." Table 8 shows a figure of 20.06 stillbirths, 21.30 neonatal deaths and 1.79 maternal deaths per thousand live births. Could the method of collecting and reporting of data by individual hospitals have influenced the accuracy of these figures? It can be claimed that the figure for these deaths cannot be in error. In this connection I shall mention a statewide study of maternal mortality which was carried out for the period from July 1, 1941 through June 30, 1942 in Minnesota. This study was a cooperative enterprise of the Minnesota State Medical Association and the Minnesota State Department of Health. One hundred and five maternal deaths were reported officially for this period. Records, however, were obtained of 112 maternal deaths. In 7 instances, the information that the death was connected with pregnancy was obtained only by matching the birth and death certificates for the period. The maternal death rate of Minnesota for the last six months of 1941 and the first six months of 1942 was roughly 2.0 per thousand live births. If the 7 additional improperly or carelessly reported maternal deaths had been included in the vital statistics, the death rate for that period would have been approximately 2.13 per thousand live births. Largely through the efforts of the late Dr. A. J. Skeel, of Cleveland, the efficient Hospital Obstetric Society of Ohio was organized about 1933. The hospitals comprising this society adopted a plan of organization of the obstetric staffs. The authority for consultation and the administration of maternal care in each member hospital was placed in the hands of a recognized head of the obstetric staff. Standards of maternal care and rules for consultation in complicated cases were set up, and staff conferences were held at which all maternal deaths were discussed. With the backing of this society the "Ohio Plan" has been a potent factor in improving maternal care in Ohio. Vital statistics show how many pregnant women die as compared to the number of living babies born during a given period of time. Dr. Skeel stated that when this formula is applied to the individual hospital it may show a false picture of the actual maternity efficiency of the hospital. From the standpoint of maternity efficiency it would be more accurate to estimate the maternal death rate among women who come to a hospital and are delivered there of a fetus of viable age; this is the delivery or obstetric mortality rate of the institution. For example, in 1931 the obstetric or delivery mortality rate in the city of Cleveland was 5.5 per thousand live births while the total maternal death rate, including all those who had live births, still births, abortions and ectopic pregnancies, was 11.1 per thousand live births. Dr. Newberger's paper is an excellent review of the obstetric activities in Illinois hospitals in 1945. The over-all record is good, but the data show a decided variance in the incidence of operative procedures, in the maternal death rate and in the data obtained from various hospitals. This implies the need for efficient organization of the obstetric staff in all hospitals accepting maternity cases and the need for more care and accuracy in keeping maternity records and in the review of such records by the obstetric staff of the hospital. I agree heartily with the recommendations submitted by the essayist.

Dr. A. E. Kanter, Chicago, Ill.: A question which often arises is: Of what value are statistics? Because statistics can be made to stand for about anything the writer wants them to. But knowing Dr. Newberger and his efficient and reliable method of analyzing statistics, we can certainly accept these as being important. Downstate shows a greater variance in morbidity, mortality and surgical procedures than does the city of Chicago. The reason for this is probably that in Chicago there is a monthly review of all mortality cases, where the operators or physicians involved are invited to a general meeting. Members of all the staffs of the hospitals may be present, and each case is taken up on the merit of the treatment; if there is an opinion that probably the treatment was not of the proper nature, a finding by this committee is sent to the physicians and to the hospitals involved. Men would be a little less likely to introduce surgical procedures when they are not indicated. Constructive criticism helps a great deal in cutting down the number of loose indications for particular treatments. From the viewpoint of teaching, the fact that the mortality and morbidity are greatest in toxemia, infection and hemorrhage, shows that the emphasis in teaching must be placed on these subjects, i. e., on the correction or prophylaxis or treatment of toxemias, hemorrhage and infection. The findings in the southern part of the state are improving primarily because a greater number of men are getting valuable training in obstetrics who settle in the smaller communities. Their efforts, plus the consultants, increase the interest of the general practitioners in obstetrics from the view point of better care and better results. They are certainly producing that result, because there is little difference between the upstate and the downstate statistics, with the exception of a few hospitals where there is little obstetric practice and probably little supervision. If this type of study is done in every state and if the hospitals will take their statistics and study them, there will be still greater improvement in the three greatest scourges in obstetrics.

Dr. Charles Newberger, Chicago: The unreliability of the data submitted by the hospitals, commented on by Dr. Mussey, was stressed in the paper. We know only too well that, unfortunately, physicians and hospital personnel generally are somewhat lax in insisting on better records. This is particularly true with reference to obstetric complications. As to the mortality: We have adopted the system whereby the hospital reports are checked with the Division of Vital Statistics, and in that fashion I believe that we have an accurate recording of the incidence of stillbirths, neonatal deaths and deaths of mothers. Dr. Kanter mentioned the Maternal Welfare Committee of Cook County. This committee studies maternal mortality of Chicago and is doing splendid work. We have talked for some time of the wisdom of instituting investigation of maternal deaths on a statewide basis. We hope that some day this will come about, and I am certain that when it does the losses of mothers and babies are going to be considerably reduced. It is essential for any individual physician to give thought occasionally to the results that he has in his professional practice. It is wise for groups of doctors on hospital staffs to do likewise. The purpose of this particular presentation was to do a similar job on evaluating and taking stock or inventory of obstetric activities and results on a statewide basis.

ABDOMINOPERINEAL PROCTOSIGMOIDECTOMY FOR RECTAL CANCER

The Management of Associated Vesical Dysfunction

HARRY E. BACON, M.D.
and
LOWRAIN E. McCREA, M.D.
Philadelphia

Abdominoperineal proctosigmoidectomy for rectal cancer is a surgical procedure that is frequently followed by complications. A survey of the various complications has revealed a series of important factors which have aided materially in the postoperative management of these patients.

These complications do not differ greatly from other types of resections on the lower bowel. During the five year eight month period ending May 1946, 480 patients with cancer of the anus, rectum and pelvic colon were examined. Of this number 440 were operated on, a rate of operability of 91.6 per cent. Resection by various methods was performed in 390 instances, a rate of resectability of 81.2 per cent. In 251 patients the technic of abdominoperineal proctosigmoidectomy was performed with 15 deaths, a mortality rate of 5.9 per cent. The rates of survival estimated on 81 patients who were followed were 58.6 per cent for three years and 50.2 per cent for five years.[1] These statistics were obtained in cases in which operative intervention was performed for palliation as well as for cure. Preservation of the sphincter musculature has offered continence estimated as 95 per cent of normal. Impotence after proctosigmoidectomy was noted as 55.5 per cent in cases in which the sphincter musculature was incised anteriorly,[2] whereas without division of the musculature the incidence of impotence was 8.3 per cent. The low incidence can be attributed to the avoidance of inadvertent trauma to the perineal structures. It is in contrast to the percentage of impotence after the Miles type of resection, which is estimated at 95 per cent.[3]

Vesical dysfunction subsequent to abdominoperineal proctosigmoidectomy for carcinoma of the rectum or sigmoid cannot be considered an incidental complication. As the surgical procedure is of relatively recent introduction, it is obvious that only a few investigators have been able to portray their observations on the occurrence or the management of this serious complication. It is conceded universally that this postoperative urinary complication to the procedure constitutes one of the major problems of management.

Those patients on whom resection has been performed return to normal living and to normal habits if the bladder can be made to function correctly. Paralytic atony of the bladder does not occur in every instance in which proctosigmoidectomy is performed, but when it does occur the vesical dysfunction portrayed by these patients is typical. There is complete urinary retention. If the retention is permitted to continue untreated and uncontrolled, dribbling of overflow develops, infection intervenes and urosepsis may occur. The urinary retention following the procedure unquestionably is due to the trauma or more often to severance of the sympathetic and parasympathetic nerve fibers (fig. 1). These fibers constitute the inferior hypogastric or pelvic plexus and innervate the internal vesical sphincter and the detrusor urinae muscle. By the removal of this plexus there is an interruption of the efferent and afferent stimuli to and from the bladder. According to Hill, Barnes and Courville[4] the nature and extent of injury to the nerve elements may vary considerably. The bladder deprived of stimulation by the interruption of the spinal arc becomes a hapless reservoir (fig. 2). Acute urinary retention with associated vesical distention occurs. The bladder musculature, suddenly relieved of all stimulating nerve impulses, rapidly becomes atonic. The walls become thin; massive diverticulation occurs; and the viscus becomes a functionless, thin-walled, irregularly shaped, dilated, noncontractable reservoir laden with infection. It is for the restoration of a normally functioning bladder that a concerted attempt has been and is being made.

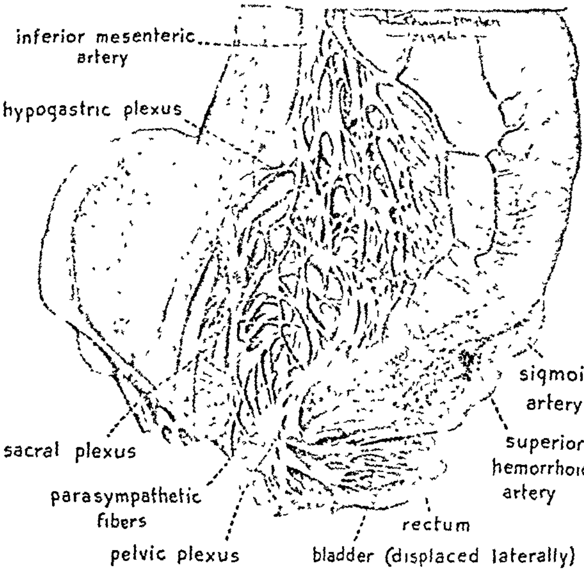

Fig. 1.—A dissection is shown of the pelvis and the ramifications of the sympathetic and parasympathetic nerves entering into the formation of the pelvic plexus.

In an investigation of the problem of vesical dysfunction after proctosigmoidectomy the departments of urology and proctology have cooperated.

Our conclusions were based on an unselected series of 251 persons on whom abdominoperineal proctosigmoidectomy was performed. In this group there were 15 deaths from causes unrelated to the urinary tract. Postoperative follow-up of 251 patients was considered. In 7 of these 251 persons vesical atony developed following the operative procedure. Of these 7 patients 5 are living and well, have returned to normal existence and urinate naturally. The sixth case is too recent to permit accurate interpretation. The seventh patient committed suicide thirteen months after the operation. An immediate psychosis developed and he continued throughout the remainder of his life to exhibit ideas

of persecution. The atonic condition of his bladder continued from the time of operation until his self-inflicted death.

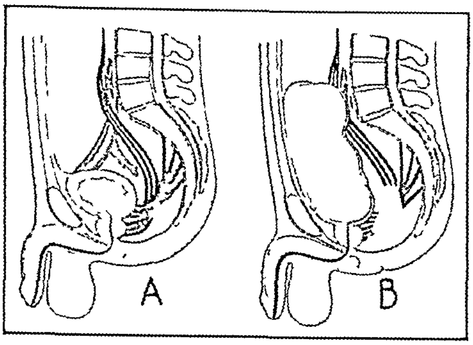

Fig 2—Schematic drawing showing the reaction of the bladder before and after removal of the pelvic plexus Following division of the nerves, the bladder becomes atonic and greatly dilated *A*, normal relationship of bladder and nerves; *B*, atonic bladder after division of the nerves

The changes in the bladder after abdominoperineal proctosigmoidectomy are occasionally dramatic. The acute urinary retention that immediately follows the surgical procedure is usually complete, although some persons may void small quantities at frequent intervals but exhibit massive amounts of residual urine. In other patients overflow incontinence may develop quickly after surgical intervention.

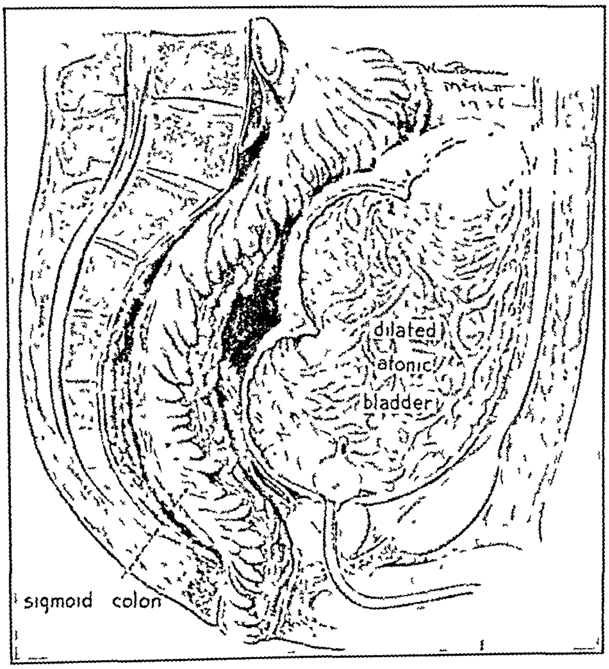

Fig. 3—The greatly dilated and atonic bladder following operation is shown The detrusor urinae cannot contract and the bladder must be continuously emptied by catheter. The rectum has been resected and the sigmoid colon has been brought down to empty externally.

An atonic state of the bladder quickly develops after surgical interference with the nerves and nerve plexus.[5] Diverticulation of the bladder rapidly occurs following the inception of an atonic state. The diverticula do not have the narrow orifices that are usually seen but are rather large outpouchings of the bladder wall. The bladder becomes irregular in contour, has a greatly increased capacity and remains an inert reservoir lined with mucous membrane (fig. 3). A state of chronic urinary retention ensues if the acute retention is not relieved continuously. Thus, two factors are constant if relief of chronic retention is not accomplished, namely, overflow incontinence and diverticulation of the bladder. Infection is invariably a factor in chronic retention. The greatest predisposing factor to infection in the urinary tract is stasis of the urinary flow, regardless of its cause. Stasis is evident in the presence of residual urine. The ischemia of the vesical mucosa during retention is another factor which fosters infection. The normal vesical mucosa is known to be extremely resistant to infection, but when it is subjected to continued ischemia its protective properties disappear and permit infection to occur.

During the surgical procedure of abdominoperineal proctosigmoidectomy, definite injury to the sympathetic and to the parasympathetic nerves occurs (fig. 4). The extremely important inferior hypogastric or pelvic plexus is subjected to injury. This plexus contains both types of nerve fibers and normally lies beneath the peritoneum on either side of the ampulla of the rectum. The internal vesical sphincter subsequent to the operation is unable to function and remains in a state of contraction because of an apparent predominant sympathetic influence; the detrusor urinae is unable to contract because of the loss of parasympathetic innervation (figs. 5 and 6). Due to the loss of innervation it has not been considered necessary to perform a transurethral resection to establish normal urination. It is to the apparent nerve imbalance that the management of vesical dysfunction subsequent to proctosigmoidectomy is directed.

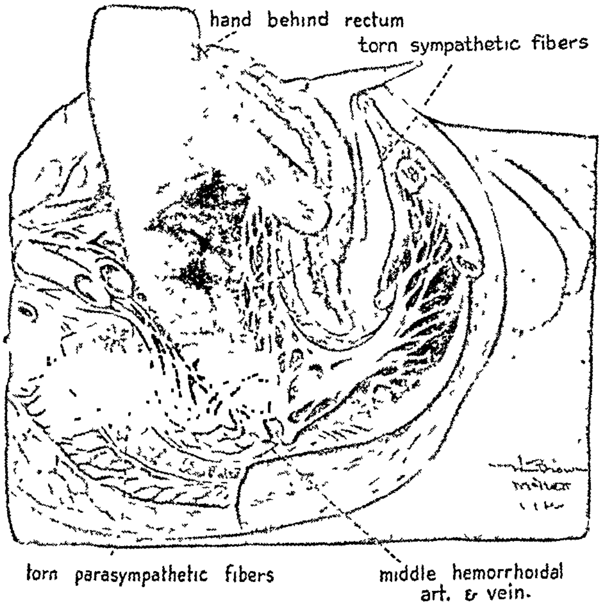

Fig 4—The sympathetic and parasympathetic nerve fibers forming the pelvic plexus are inadvertently torn by the surgeon while freeing the attachments of the sigmoid and the rectum

INFECTION OF THE URINARY TRACT

Infection of the bladder is a factor that should always be subjected to the most rigid control. In a survey of 58 cases in which urine was taken for culture before operation, a negative report was returned for 18. Of these, in 15 cases samples of urine were demonstrated by culture to have remained sterile throughout the period of operation and postoperative convalescence. It was surprising to learn that in 40 cases (of the total of 58 cases, or 68.9 per cent) the original culture revealed a positive growth.[6] The bacteriologic findings of these cultures was not unusual. Streptococci were observed in 10, staphylococci in 9, Escherichia coli in 6, Bacillus pyocyaneus in 2, Proteus vulgaris in 1 and fungi in 2. The remaining 10 cultures revealed a mixed growth. There were only 3 instances in which the culture was primarily negative and became positive postoperatively. In these 3 instances the infecting organism was Staphylococcus albus. In spite of the number of positive cultures none of the patients required specific treatment for relief of symptoms. It is believed that phthalylsulfathiazole (Sulfathalidine) which is routinely administered during the preoperative management for bowel surgery is an important factor in the control of infection of the urinary tract. Poth and Ross [7] have demonstrated sterile urine in three to nine days after the oral administration of the drug.

MANAGEMENT OF VESICAL DYSFUNCTION

Beyond question, the best method of preserving the musculature of the bladder and preventing vesical atony is to maintain a bladder at rest. The rest should be complete and should be maintained until the bladder has regained its ability to function normally. An indwelling catheter properly introduced is preferred to cystotomy drainage in maintaining a bladder at rest. Vesical atony should be anticipated in every instance in which abdominoperineal proctosigmoidectomy is done, and steps should be taken to control such vesical dysfunction before it ever occurs. The routine for e preoperative and postoperative management that has een found satisfactory is as follows:

Preoperative.—A urine culture is taken at the time ystoscopy and cystometry is done. Cystoscopy is of onsiderable aid in determining vesical involvement by he carcinomatous mass. Cystometry preoperatively ys a foundation for further observance and management of vesical activity. Although the great majority f patients have shown a normal cystometrogram, a certain percentage have revealed a hypotonia before operative intervention. It has been surprising to learn that those patients who exhibit vesical hypotonia preoperatively have been found to have an infiltrating lesion at or in the immediate vicinity of the ampulla of the rectum, the site of the pelvic plexus. To maintain a bladder at rest a catheter is inserted into the bladder immediately before the operation.

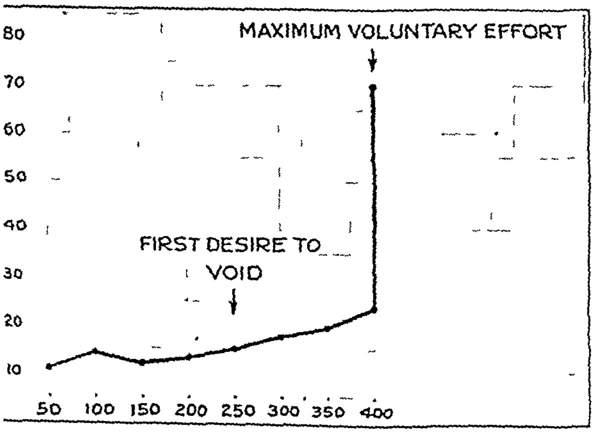

Fig 5.—Normal cystometrogram There is a gradual rise of pressure o a point varying between 20 and 30 cm with a fill of 400 cc. of solution The first desire to void occurs usually with 250 cc. of fill. A maximum voluntary pressure of 70 cm. is usual

Postoperative.—Irrigation of the bladder by means of solution of boric acid is performed twice a day. Urine cultures are taken on the fourth and tenth postoperative days at the time cystometry is done. Cystometry permits an accurate interpretation of the patient's ability to void. If the patient is capable of exerting voluntary pressure of 70 cm. on the tenth day, the catheter is removed and the patient is instructed to void. If the patient voids, a catheter is reinserted immediately and the presence or absence of residual urine is ascertained. If more than 60 cc. of residual urine is present the catheter is permitted to remain in situ until the bladder is capable of more complete emptying. If the patient is unable to void, Syntropan (200 mg.) is administered orally three times a day to decrease the tone of the smooth muscle of the internal vesical sphincter. Repeated cystometric readings are subsequently taken to determine the functional ability of the detrusor urinae. The Syntropan is continuously administered until normal voiding occurs. In not a single instance, except in 1 patient who exhibited evidence of psychosis, has there been failure to resume normal urination.

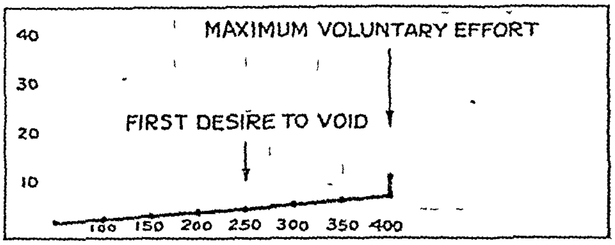

Fig 6.—Hypotonic cystometrogram This is a typical curve following proctosigmoidectomy when vesical atony occurs There is a gradual rise to 10 cm or below with 400 cc. fill The first desire to void may vary greatly or may not be experienced by the patient The maximum voluntary effort is slight Urination is impossible, as the detrusor urinae cannot contract because of the lack of innervation

SUMMARY

1. A résumé of the management of vesical dysfunction in 244 patients with rectal carcinoma who were subjected to proctosigmoidectomy has been presented.

2. Paralytic atony of the bladder with retention of urine occurs frequently after resection of the rectum for carcinoma unless measures are constantly taken to prevent it.

3. Vesical dysfunction following proctosigmoidectomy is due to trauma or the inadvertent removal of the inferior hypogastric or pelvic plexus. For this reason transurethral resection has not been performed in a single instance.

4. There were 7 instances in 244 cases in which normal micturition was impossible at the time of discharge from the hospital. Of these 7 cases, 5 returned to normal voiding and are without residual urine. One became insane and committed suicide thirteen months after operation. One case is too recent to evaluate.

5. The best possible procedure to maintain normal musculature is to maintain a bladder at rest. This may be accomplished by continuous drainage with a catheter.

6. Urinary retention may be transitory or may be present for days, weeks or even months. Urinary retention may be permanent if paralytic vesical atony occurs.

[7] Poth, E. J., and Ross, C A · Clinical Use of Phthalylsulfathiazole, J. Lab & Clin. Med **29**:785, 1944.

7. Positive urine cultures do not always denote cystitis, but a constant guard against cystitis should be maintained. It is believed that phthalylsulfathiazole (Sulfathalidine) administered routinely in preparation for bowel surgery exerts a bacteriostatic effect on organisms found in the urinary tract.

8. The oral administration of 200 mg. of Syntropan for its effect on decreasing the tone of the smooth muscle of the internal sphincter has been found to aid in reestablishing normal urination when the tone of the detrusor urinae is normal.

9. The existence of a collateral sympathetic nerve supply is considered as a possibility in creating the nerve imbalance which is so evident following surgical intervention.

10. To May 6, 1947, 140 consecutive resections have been performed without a death.

ABSTRACT OF DISCUSSION

Dr. Curtice Rosser, Dallas, Texas: We are no nearer to agreement concerning the mechanism of this complication. Dr. Bacon is convinced that injury of the nerve supply is entirely responsible, agreeing with Dr. T. E. Jones. Yet Coller and his associates and more recently Marshall, reporting from the New York Memorial Hospital, have stated that endoscopic examinations and cystograms disprove the neurogenic theory. Marshall believes that widespread and bilateral denervation would be required to bring about long continued dysfunction. Marshall and his associates found that the percentage of patients with severe urinary difficulty (8 per cent lasting over three months) was approximately the same whether combined abdominoperineal or posterior resection only was done. They concluded that the dysuria is due to a sag of the bladder, bladder neck and prostate resulting from the dissection at the base of the bladder and removal of the support of the rectosigmoid colon, with consequent alteration of the arrangement of the urethra and external sphincter of the bladder. One of their patients was completely relieved by surgical elevation and fixation of the bladder. I have reviewed a consecutive series of 100 cases, terminating last March 1, in which different technics were used. There were 92 cases of abdominoperineal resection, 3 in two stages, 6 of a one stage anterior resection, as described by Rankin, and 2 of perineal resection following colostomy. Forty-three per cent of the patients were women, and it is noteworthy that while temporary dysuria occurred in a number of the women, in none did it continue for a long period, which agrees with my previous experience. It was found that voiding in the upright position with the torso bent forward was a helpful device for these patients. Excluding these 43 women and the 5 patients who died as a direct result of the surgical procedure, 52 male patients remained. Of this group 6, or 11.5 per cent, had dysuria which continued more than three months. One of these men, whose ureter had been severed, was cured by ureteral repair. Another, whose prostate had been a matter of concern for ten years before he submitted to surgical intervention, still defends its integrity from the urologist. One patient had his prostate removed three years after his rectal resection, at the age of 75. The third had an unmistakable "cord bladder" of neurogenic origin, which was relieved but not cured by resection of the median lobe. In the only patient with definite urinary incontinence, the symptoms persisted until his death from local recurrence some months later. One patient had a transurethral resection in the hope of relieving pain, which later was found to be due to recurrence involving the bladder. The last patient, an elderly man, was entirely relieved by prostatectomy. Since the presence of an indwelling catheter for long periods is not without danger, it is urged that after the first removal of the catheter the presence of residual urine be checked for several days, using a firm small coudé catheter to avoid injury and this procedure be continued until the bladder demonstrates its ability to completely expel its contents.

Dr. Roger W. Barnes, Los Angeles: The large series of cases on which their conclusions are based make the paper of Drs. Bacon and McCrea most valuable. It is surprising that in so few of their patients did there develop a vesical hypotonus following abdominoperineal proctosigmoidectomy—only 7 of 244, an incidence of 2 per cent. In answer to a questionnaire sent by Dr. Malcolm Hill in 1937, more than half of 59 leading proctologists reported that over 50 per cent of their patients had vesical dysfunction after this operation, and 32 of the 59 who answered the questionnaire stated that two thirds or more of their patients had disturbances of the bladder. It is probable, therefore, that most surgeons have a higher incidence of this complication than is reported by Drs. Bacon and McCrea. Some surgeons have advanced the theory that nerve injury is not the cause of vesical dysfunction following abdominoperineal proctosigmoidectomy. A study of the postoperative bladder in these patients, however, reveals all the characteristics of the neurogenic bladder—a rounded deformity of the dome in the cystograms, a hypotonic curve by cystometric study, as Dr. McCrea has shown, and relaxed posterior lip of the bladder neck as seen through the cystoscope. The management of the bladder in these instances is important, and the use of the indwelling catheter as described by Drs. Bacon and McCrea is to be recommended. Their evaluation of the tone of the bladder by cystometric study to determine the proper time for removal of the catheter is an innovation and adds to the accuracy with which these patients can be treated.

Dr. Lowrain E. McCrea, Philadelphia: I wish to thank Drs. Rosser and Barnes for their comments. We agree that the cause of vesical atony is a rather controversial subject. We also agree that a great many of the patients on whom proctosigmoidectomy is performed are in the prostatic age and that a certain percentage of them have prostatic hypertrophy or obstruction of the vesical neck in varying degrees. There is no argument at all in the management of these cases. If a man has a prostatic obstruction there is only one answer—to take it out. The method of procedure for the prostatic removal is that of individual choice as governed by each patient. We believe that a bladder having obstructive factors shows increased vesical dysfunction following such an operation as proctosigmoidectomy because of the lack of normal nerve influence. The cases of vesical dysfunction which we have considered are only those in which the patients presented a normal cystometrogram before operative intervention, were without obstructive uropathy, were subjected to abdominoperineal proctosigmoidectomy and showed decided alteration of the cystometric curve immediately after the surgical operation. The alteration of the cystometrogram and the vesical dysfunction continued over a period of weeks and in some instances several months. Undoubtedly there is considerable damage to the innervation to the bladder during such a procedure as proctosigmoidectomy. The innervation of the bladder and lower part of the pelvis is not thoroughly understood, and considerable interference with the inferior hypogastric or pelvic plexus occurs in the operating room, with subsequent alteration of the function of the bladder in some instances.

Effect of Flies on Milk Production.*—In order to find out* how much the farmer really benefits by controlling flies on range cattle, the Department of Agriculture cooperated in a large scale test with the state people in Kansas. A similar test was made in Florida on dairy cattle. They found that in the range herd where the flies were controlled with DDT the weight gain during the summer averaged 50 pounds more, per animal, than in a similar herd where no spraying was done to control the flies. In the Florida experiment with the dairy cows we found that the cows gave 10 to 15 per cent more milk when the flies were controlled. About $50,000 was spent in these experiments on DDT. There's already a profit of $10,000,000, with a possibility of reaching at least $100,000,000 every year.—Lambert, W. V.: Research Yields Billions, *Science News Letter*, April 12, 1947.

Clinical Notes, Suggestions and New Instruments

INTRAOCULAR PENICILLIN IN SEVERE INTRAOCULAR INFECTION

Report of Case

LOUIS R. HAAS, M.D.
Pittsburg, Kan.

Recently there have been a number of reports on the use of penicillin in endophthalmitis and panophthalmitis. The results obtained by its use in this case, however, were so dramatic and so surprising that they are worthy of being reported.

The patient, a boy aged 10, was chopping wood when he was struck with a piece of wood just nasally and below the center of the left cornea. Twenty-four hours later he consulted his family physician, who referred him to me. Thus the accident had happened about thirty-six hours before I saw the patient.

Examination of the left eye revealed a decidedly injected, chemotic eye, with a perforation about 2 mm. long just temporally and below the center of the left cornea. The wound was ragged, and there was a yellow infiltrate in the cornea completely surrounding the wound. The lower half of the anterior chamber was filled with a hypopyon. There was a gelatinous membrane across the upper part of the pupil, which was all of the pupil that could be seen. The aqueous humor above the hypopyon was gelatinous and filled with shreds. The iris was greatly congested and appeared to be plastered against the anterior lens capsule with a plastic exudate. The fundus could not be seen.

The lids were edematous, and saving the sight of the eye, which was extremely painful, seemed to be impossible. The patient was admitted to the hospital. He was given 3,000 units of tetanus antitoxin. Penicillin was given intramuscularly every three hours, 20,000 units. The aqueous humor was allowed to escape by depressing the lips of the wound with a probe, and the anterior chamber was filled with a solution of penicillin, 500 units to the cubic centimeter, using an ordinary hypodermic syringe and needle through the wound. This procedure was carried out at 6 p. m. Atropine was instilled into the eye. The application of hot compresses and penicillin ointment every three hours was ordered to be continued until the next morning. At this time the hypopyon had disappeared, but the iris was plastered against the lens, the pupil was covered with a plastic exudate and the aqueous humor, which was full of shreds, appeared gelatinous. The chemosis and injection had subsided little if any. The pupil had been dilated but little. A 10 per cent solution of neo-synephrine hydrochloride was added to the atropine instillations, three times a day. Again, the anterior chamber was evacuated by depressing the lips of the wound with a probe, and the aqueous humor was again replaced with a solution of penicillin. Hot compresses were continued. That evening there was definite recession of the chemosis and injection, the edges of the wound were much cleaner and the pupil was well dilatated. There was some pigment and exudate adherent to the pupillary area of the anterior capsule, and a long fibrinous string of exudate was attached to the cornea at the area of the wound. A blunt forceps which was inserted through the wound grasped and removed this string of exudate. Some aqueous humor was lost. The remaining aqueous was again evacuated, and penicillin was injected. The instillation of atropine was now reduced to once a day, and the application of hot compresses was continued. The following morning, except for a dilatated pupil and a slight amount of pigmented exudate clinging to the center of the anterior lens capsule, the eye was to all appearances a perfectly normal one with a clean puncture wound and little ciliary injection. The chemosis was gone. Again the anterior chamber was evacuated, and penicillin was injected.

This time, however, it is probable that too much solution was put in, as the patient had great pain for an hour after its injection. The eye, which from then on appeared normal except for a normally healing scar of the cornea and an ever decreasing exudate on the anterior capsule, was watched carefully for one month. The patient was dismissed from the hospital three days after his admission; he continued to use penicillin ointment and hot compresses three or four times a day at home. The eye was kept covered for a week.

One month later the eye exhibited a small corneal scar just up to the edge of the undilated pupil, and the patient's vision, uncorrected, was 20/20 in the right eye and 20/25 in the left eye. After the instillation of atropine his vision required the following correction: right eye-25x15, left eye-25-25x155. With this correction, the patient's vision was 20/15 in either eye. There remained a few spots of pigment where the iris had been adherent to the lens, which were visible only under magnification.

The evacuation of the chamber and the injection of penicillin were done while the patient was in bed, under tetracaine hydrochloride anesthesia. Unfortunately cultures were not made, so the causative organism is not known. I feel confident that this eye would certainly have been lost if penicillin had not been available. And if such a result can be obtained in a traumatized eye, there is no reason to suppose that the same result could not be hoped for in treatment of infection following surgical intervention, provided the organism is sensitive to penicillin.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following report.
Austin Smith, M.D., *Secretary.*

DRUGS FOR OBESITY

The control of obesity is difficult because patients usually demand treatment that would produce miraculous changes in appearance almost overnight and refuse to abide by a scientific reduction of diet necessary for the average case. The overweight are therefore easy prey for the distributors of questionable preparations offered as specific antiobesity drugs. Years ago such preparations were characterized by flamboyant claims for curative properties. Today, because of the activities of federal agencies concerned with the control of drug manufacture, labeling and advertising, the claims are worded more cautiously but the implications frequently remain the same. Too often some physicians are duped into recommending some medicament that is offered with more enthusiasm than scientific support.

From time to time the Council on Pharmacy and Chemistry, the Bureau of Investigation and The Journal have drawn attention to the more objectionable preparations. Frequently the substances have contained essentially stimulants, hormones such as thyroid, laxatives or a mixture of these drugs. In spite of the teaching of the best informed physicians and of the vigilance of the American Medical Association and other agencies, preparations of this class continue to be exploited.

The Council on Pharmacy and Chemistry has accepted for inclusion in N. N. R. amphetamine and amphetamine sulfate with certain well defined uses (see New and Nonofficial Remedies, 1946, p. 279). It has not accepted mixtures of amphetamine and other potent agents. Such potent drugs must be administered according to the needs of the patient and cannot be offered in a fixed formula with the belief that the majority of patients will benefit from fixed ratios. Nevertheless a firm by the name of Clark & Clark of Wenonah, N. J. has promoted such mixtures as amphetamine sulfate, thyroid, atropine sulfate and aloin. How reminiscent this practice is of the days of shotgun mixtures in pharmacy.

In the files of the Council is an interesting accumulation of advertising that has been offered from time to time on behalf of the Clark & Clark preparations Profetamine and Clarkotabs. According to an advertisement in the April 1946 issue of the *Bulletin of the Philadelphia Association of Retail Druggists* Profetamine Sulfate Tablets are a brand of racemic amphetamine sulfate. This advertisement bears the interesting eye-attracting headline "Accepted!" although an asterisk refers the reader to much smaller print which reveals that the preparation is "accepted by thousands of leading physicians throughout the country." In view of the significance of the word "accepted" in ethical advertising, one wonders concerning the motives of the writer of this advertisement when this word was included in the copy.

Clarkotabs, according to an advertising card having the mailing date Dec. 20, 1946, is "The Original Triple-Formula Obesity Preparation." The card bears in part the following revealing formulas:

Formula No. 1—Grey

Amphetamine Sulfate	5 mgm.
Thyroid	1 gr.
Atropine Sulfate	1/360 gr.
Aloin	¼ gr.

Formula No. 2—White

Amphetamine Sulfate	5 mgm.
Thyroid	1 gr.
Atropine Sulfate	1/360 gr.

Formula No. 3—Pink

Amphetamine Sulfate	5 mgm.
Thyroid	1 gr.
Phenobarbital	¼ gr.

As if this shotgun approach to the problem of obesity was not a sufficient insult to the intelligence of the medical profession, the advertisement previously referred to offers Profetamine Sulfate Tablets " as a supplement to Clarkotabs in certain stubborn obesity cases." The cases must certainly be stubborn if they would not respond, one way or another, to a mixture such as amphetamine and thyroid!

More recently "Clarkotabs" have been advertised to physicians and pharmacists under the name "Clarkotabs Modified," in which Formulas No. 1, No. 2 and No. 3 have apparently been "modified" by substituting n-methyl amphetamine hydrochloride for amphetamine sulfate. Presumably the modified tablets are available in either the colors of the old formulas—gray, white and pink—or an eye-dazzling new combination of green, blue and yellow. In the November-December 1946 issue of the *Bulletin of the Philadelphia Association of Retail Druggists* is a full page advertisement for Clarkotabs Modified, opposite which is another page-wide announcement to the effect that Clark & Clark has decided to use desoxyephedrine hydrochloride in its formula "instead of the probably less active or less desirable amphetamine sulfate." According to the firm, this change, "even though it is made in the interest of better and more precise therapeusis of obesity, will probably be of temporary duration because Clark & Clark has had under extensive clinical and toxicological study for quite some time a *new, different* and *more physiologic* amphetamine derivative than any hitherto available." This dramatic and what the firm probably considers awe-inspiring statement is concluded with the following note:

> The new amphetamine derivative shall also be available, plain, for use wherever a better and more physiologic amphetamine compound is indicated. Clark and Clark will keep you and the medical profession properly and promptly informed on any and all progress in this field.

If there are any members of the medical profession who are breathlessly awaiting a remarkable new contribution to therapeutics, they may take a few relieving inhalations, as confidential information reaching the Council suggests that the compound that is being investigated will never set the world on fire.

Some indication of the philosophy of the individuals who promoted such advertisements as the one in the November-December issue of the P. A. R. D. *Bulletin* is shown by the fact that n-methyl amphetamine and desoxyephedrine are actually chemical synonyms, which the firm did not bother to explain in its advertisement despite its concluding resolution that it will keep the medical profession "properly and promptly informed."

Clark & Clark indicate that its adoption of a change in formula was based on recommendations of its Department of Research and Clinical Investigation and on the work of Novelli and Tainter.[1] The latter observed in 1943 that dextro methyl benzedrine (desoxyephedrine) had less circulatory action and no less, or possibly greater, central stimulant action than amphetamine. Perhaps the firm wishes the reader to infer that its Research Department was righteously cautious in waiting three years to select desoxyephedrine to replace amphetamine in its formulas for obesity. One cannot help but wonder, however, concerning the significance of recent news of legal action brought against Clark & Clark by Smith, Kline & French Laboratories of Philadelphia for infringement of its patent on amphetamine sulfate. In the Feb. 17, 1947 issue of *Drug Topics* on page 47 is a full page notice sponsored by Smith, Kline & French Laboratories. This notice is headed "U. S. Supreme Court Denies Petition of Clark & Clark to Review Decision of U. S. Circuit Court of Appeals in the Amphetamine Sulfate Case" and reads in part "A permanent injunction prohibiting, until the patent expires, all further manufacture and sale of amphetamine sulfate in medicinal preparations, *which include obesity combinations*, has been issued against Clark & Clark, Charles L. Morris and Robert B. Morris trading as Professional Laboratories." (See end of this report.)

What originality Clark & Clark can claim for Clarkotabs is apparently that of mixing amphetamine with other potent drugs to depress the appetite and on foisting this kind of quackery on the physician and pharmacist rather than on the less informed public. No one can dispute the need for studying closely every patient to be treated for obesity and to prescribe treatment specifically for the individual. Such an unscientific combination of drugs as is represented by mixtures of amphetamine sulfate, thyroid, atropine sulfate, aloin and phenobarbital merits no more than casual comment. Amphetamine appears to suppress the appetite, while thyroid increases fat metabolism. But, as Freed[2] points out, "Thyroid therapy in most cases is of little value" and "often the dose approaches toxic levels." If thyroid is needed occasionally for those who show signs of thyroid deficiency, it should be prescribed to meet the needs of the individual case and not offered promiscuously. Atropine possibly may render the food unpalatable by drying secretions of the mouth, and aloin could be expected to produce cathartic action. Cathartics have long been employed in nostrums for obesity. If something is needed to offset the constipation that may follow prolonged amphetamine sulfate therapy and restriction of diet, more simple lubricants could be prescribed, again to suit the needs of the patient. The fallacy and dangers of overstimulating the body with thyroid and of using laxatives to aid in reduction are well known to the medical profession. Phenobarbital may have been included as a sedative to mask the unpleasant effects of this irrational mixture.

However, Clark & Clark can make few if any claims of originality for weight reduction mixtures. The advertising files of practically any active organization associated with protection of the health of the general population contain specimens of equally objectionable mixtures. For example, in the Council's files one may learn that the Western Research Laboratories of Denver has advertised to physicians a method of treatment for obesity involving the use of tablet combinations of thyroid and digitalis in varying proportions. These tablets were marketed as Thyrodig Tablets No. 1, No. 2 and No. 3, along with Herb Tablets of aloin, cascara and rhubarb compound. A circular entitled "Method of Treatment for Obesity" begins with the fascinating statements "Our treatment for Obesity consists of two types of medication, each in varying amounts, to suit the individual case. We give a gland tablet in the morning and an herb tablet at bedtime" and offers the advice "Six Points to be Remembered: 1. Recommend NO Diet or Exercise. 2. See your patient ONLY once per month. 3. Fill in the complete chart at each visit, using our symbols to designate the medication. 4. Give each new patient complete instructions as to what they may expect from the treatment. 5. Give plenty of the Herb tablet, most obese patients are constipated. 6. Get cash for the treatment, carry no charge accounts."

Another outfit, Morton Pharmaceuticals, Inc., of Memphis, Tenn., has circularized at least part of the medical profession with a form letter warning "F A T can be D-A-N-G-E-R-O-U-S," making reference to a report by Dr. Frederick K. Albrecht of the U. S. Public Health Service. Dr. Albrecht did not give permission for the use of his name. Such unauthorized use of names is to be deplored and the users severely censored. The type of therapy proposed by the Morton company, according to a circular reaching the Council office, consists of O-B-E-C Treatment, for which there are two types of tablets. O-B-E-C Tablets FORMULA A are claimed to contain dl-desoxyephedrine gr. 1/12, Thyroid, U. S. P. gr. 1, Atropine Sulfate gr. 1/350; O-B-E-C Tablets FORMULA B are claimed to contain Phenobarbital gr. ¼, Rochelle Salts gr. 5, Aloin, gr. ¼. Apparently Clark & Clark is not the only concern interested in promoting desoxyephedrine as a constituent of a mixture for the treatment of obesity.

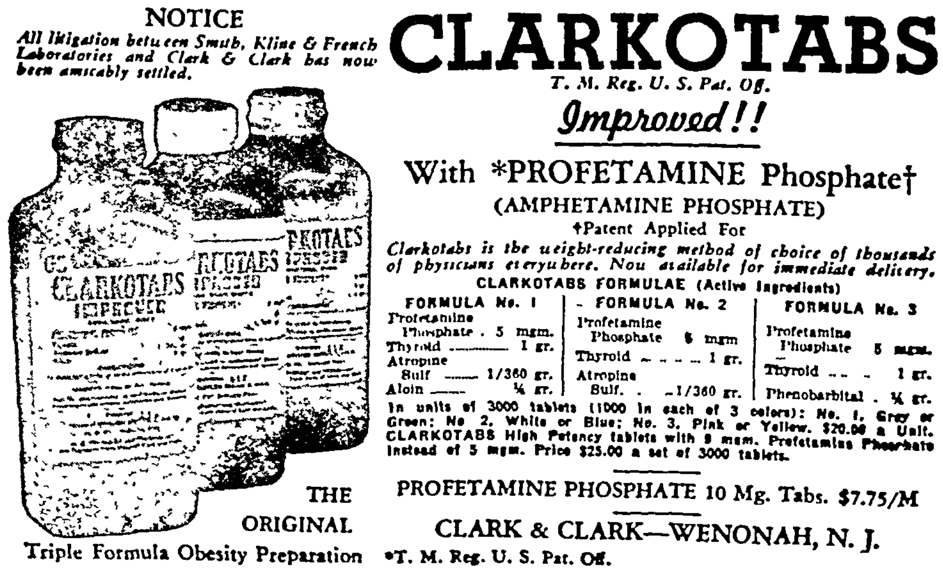
[2] Freed, S. Charles: Psychic Factors in the Development and Treatment of Obesity, J. A. M. A. **133**: 369 (Feb. 8) 1947.

Still another concoction for obesity is "Thyrop," marketed by the Cole Chemical Company. Each capsule is stated to contain "Thyroid Substance 1 gr., Pituitary (Whole) ⅛ gr., Ferrous Sulfate ¼ gr., Ext. Phytolacca ½ gr., Ext Apocynum ¼ gr., Sodium Bicarbonate 2½ gr., Potassium Bicarbonate 1¾ gr., Calcium Phosphate 1⅓ gr., Calcium Glycerophosphate ⅔ gr." This classic example of a "shotgun" mixture is advertised to physicians for "obesity of endogenous nature or when associated with depressed metabolic function," with a recommended average dosage of one to two capsules three or four times a day, thus representing a dose of from six to eight grains of thyroid daily. The inclusion of Phytolacca and Apocynum places the product fully in line with others of this class, the use of which has been so long and so many times condemned

From time to time the medical profession must expect to be deluged with advertising material that promises therapeutic miracles for treatment with a minimum of undesirable responses. Physicians should examine carefully every preparation that is extolled to them for use and when in doubt concerning the efficacy of a preparation seek information from authoritative sources. Therapeutics has progressed too far and there are too many truly worthwhile agents available for prescription to warrant any physician lending his cooperation to irrational therapeutics.

ADDENDUM

Since the above report was prepared, certain additional information has been published which throws further interesting light on the case of Clarkotabs vs. rational therapeutics. This information bears out the contention of the report that the chief, if not the only benefit of the company's change from amphetamine sulfate to amphetamine phosphate ("profetamine phosphate") was as an instrument of attacking or evading the amphetamine sulfate patent. Present published information indicates that this object is now being attained According to the subjoined postcard advertisement of Clark & Clark, "All litigation between Smith, Kline & French Laboratories and Clark & Clark has now been amicably settled" and Clark & Clark may market their Clarkotabs without fear of legal prosecution; but it will be noted on the card that the formulas are identical with those of the original Clarkotabs except that the phosphate is replacing the sulfate



NOTICE

All litigation between Smith, Kline & French Laboratories and Clark & Clark has now been amicably settled.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

PENICILLIN (See New and Nonofficial Remedies, 1946, p. 212).

The following additional dosage forms have been accepted:

Premo Pharmaceutical Laboratories, Inc., New York

Crystalline Penicillin Sodium: 20 cc. vials containing 100,000 units or 200,000 units.

Schenley Laboratories, Inc., Lawrenceburg, Ind.

Penicillin Sodium: 1,000,000 units in 100 cc. vials.

CRESATIN-Sulzberger (Meta-cresylacetate) (See New and Nonofficial Remedies, 1946, p. 113).

The following additional dosage form has been accepted:

Sharp & Dohme, Inc., Glenolden, Pa.

Cresatin Metacresylacetate (Sulzberger) Ointment: 7.1 Gm. tubes. Contains metacresylacetate 80 per cent, with benzoic acid and ethyl-cellulose.

CAROTENE (See New and Nonofficial Remedies, 1946, p. 613).

The following additional dosage form has been accepted:

Wyeth Incorporated, Philadelphia

Capsules Carotene Concentrate in Oil: Each capsule contains an amount of carotene equivalent to 5,000 U. S. P. units of vitamin A.

HOMATROPINE METHYLBROMIDE (See New and Nonofficial Remedies, 1946, p. 314).

The following dosage form has been accepted:

Endo Products, Inc., Richmond Hill, N. Y.

Mesopin Tablets: 2.5 mg.

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1946, p. 395).

The following dosage form has been accepted:

William H. Rorer, Inc., Philadelphia

Solution Theophylline Ethylenediamine: 0.24 Gm. in 10 cc. ampuls.

PERTUSSIS VACCINE AND ANTITOXIN COMBINED WITH DIPHTHERIA TOXOID.—Pertussin Endotoxoid Vaccine with Diphtheria Toxoid.—A suspension of pertussis vaccine in a solution of pertussis antitoxin, made from Hemophilus pertussis phase I organisms combined with diphtheria toxoid. The bacterial suspension is prepared after the technic of Kendrick and Eldering, the bacterial solution by the Strean method, and the diphtheria toxoid is standardized in accordance with the requirements of the National Institute of Health.

Actions and Uses.—For active immunization against pertussis and diphtheria. It is not intended for treatment or for the production of immunity once exposure has taken place.

Dosage.—See under Pertussis Vaccine and Antitoxin Combined and under Diphtheria Toxoid

Ayerst, McKenna & Harrison Ltd., New York

Pertussis Endotoxoid-Vaccine with Diphtheria Toxoid: 10 cc. vials. Each cubic centimeter contains 25 billions of H. pertussis organisms and antigen derived from approximately 25 billion H. pertussis organisms, together with one immunizing dose of diphtheria toxoid. Preserved with Merthiolate 1:10,000.

SATURDAY, JUNE 7, 1947

THE CENTENNIAL STAMP

On June 9 the third assistant postmaster general, Mr. Joseph Lawler, will present to the House of Delegates of the American Medical Association the stamp issued by the Post Office Department of the United States commemorating the work of the physician; it is issued as a part of the celebration of the birth of the American Medical Association one hundred years ago.

The stamp is a three cent stamp which reproduces the painting "The Doctor" by Sir Samuel Luke Fildes, R.A. The original study for this painting hangs in the Guthrie Clinic of the Robert Packer Hospital in Sayre, Pa. It was presented to the hospital by Mr. Allan P. Kirby. Through the kindness of the hospital this original study will be exhibited in the auditorium at the Centennial Celebration.

The large painting called "The Doctor" which hangs in the Tate Gallery in London was painted from this original study. The physician in the painting is Sir James Clark, F.R.S., K.C.B., who was a physician to the royal family in Great Britain and well known as a scientist and educator. He was also physician to Prince Leopold, later king of the Belgians. He published "De frigoris effectibus" in 1817 and a book entitled "Notes on Climate, Diseases, Hospitals and Medical Schools in France, Italy and Switzerland" in 1820. In 1835 he published his work entitled "Treatise on Pulmonary Consumption," and he also published a book in Italian entitled "Medical Education at Edinburgh." Sir James Clark was born in 1788 and was made a Knight Commander of the Bath in 1866. He died in 1870 at the age of 82.

The painter Sir Samuel Luke Fildes, R.A., chose to portray Sir James Clark not as physician to the Queen but at the bedside of a child of a rural family. He worked many months on this painting. Apparently he had the interior of the cottage shown in the painting reproduced in his own great studio, and walls, windows and even rafters were properly placed before he began to paint. The furniture was also actual furniture used in the studio as part of the model for this picture.

Great interest has attached to the issuing of the stamp. A special ceremony is to be held in New York with a broadcast on the radio. Several of the exhibitors at the annual session have arranged to supply physicians with envelops carrying the stamp as well as first day covers; some of the philatelic societies are also holding special ceremonies.

REDUCTION TIME OF BLOOD

The need for a simple, direct method for estimating the rate of utilization of oxygen by the tissues is obvious. A recent series of investigations[1] suggests an ingenious method based on the rate at which oxyhemoglobin is reduced in the tissues. Spectroscopy of light reflected from the skin will show the characteristic absorption bands of oxyhemoglobin. Also it has been shown[2] that venous compression and resulting hemostasis tend to obliterate the bands of oxyhemoglobin as it is changed to reduced hemoglobin. Under carefully controlled conditions, therefore, the rate of disappearance of the absorption bands of oxyhemoglobin might serve as an index to the rate of oxygen utilization of the skin or tissue examined and this perhaps in turn to the metabolic rate of the subject. Use was made of this principle for determining oxygen consumption by Vierordt[3] in 1878.

An ingenious device for occluding the blood vessels of the hand by an ordinary sphygmomanometer cuff and examining reflected light from the skin of the first interosseous space by a spectroscope has been described in detail.[4] The rate at which the absorption band at 577 millimicrons disappears is then carefully determined in duplicate by a stop watch. The mean reduction time for 317 normal resting subjects was found to be 37.7 seconds, the minimum and maximum values being 25 and 60 seconds respectively.

As the author suggests, the reduction time represents not solely the time required for the utilization of oxygen but also the time necessary to approximate capillary stasis and perhaps other factors. There was a close correlation between alveolar oxygen tension and the reduction time and a less definite but significant relation to systolic and diastolic blood pressures. Nervous disturbances and breath holding likewise were found to affect the value. Thus, as might be expected, factors influencing respiration and circulation affected the reduction time even under the carefully controlled conditions employed. Of greatest clinical interest, however, is the fact that there was a definite relationship (inverse) to the basal metabolic rate. Of the 71 subjects studied, those showing a low basal metabolic rate also showed a prolonged reduction time, whereas those having a metabolic rate in the higher normal range showed a shorter than average reduction time.

---

[2] Edwards, E. A., and Duntley, S. Q.: Am. J. Anat. **65:** 1 (July) 1939.

[3] Vierordt, K.: Ztschr. f. Biol. **14:** 422, 1878.

[4] Ray, G. B.: Am. J. Physiol. **147:** 622 (Dec.) 1946.

As the Long Island workers state, the reduction time of oxyhemoglobin in the skin represents a complicated physiologic measurement. However, in view of the high degree of correlation with the basal metabolic rate, it appears possible that, with sufficient care in technic and intelligence in interpreting results, this novel procedure might prove of considerable value as a rapid, single method for approximating the rate of oxygen utilization in human subjects. Certainly the problem merits further careful study.

SEWAGE DISPOSAL FROM RAILWAY CONVEYANCES

Barringer[1] expressed concern in 1903 over the infection of the roadbeds of American railways through the discharges of typhoid patients traveling over the road while in the infective stage. He argued that "in the well drained but cool and moist soil under the ties and ballast of the modern railway roadbed, baptized day after day and year after year with the albuminous fluids of human excrement, the Bacillus typhosus, once planted in this natural culture medium, will live forever, revitalized at intervals by new infection, perhaps, but in the meantime facultative enough to meet seasonal and other changes." Maxcy[2] now reviews the evidence that has accumulated in a half century of experience since the hypothetical existence of this menace from railways was recognized. The study represents an extensive review of the epidemiologic experience with typhoid in relation to railway sanitation in this country and other countries, particularly Germany, Switzerland and England.

During the years 1906, 1907 and 1908 the United States Public Health Service conducted a detailed epidemiologic investigation. The maps show the Pennsylvania and the Baltimore and Ohio railroads entering and leaving the city from the northeast and northwest, with railroad yards and terminal facilities. Careful examination of these maps and tables indicated no apparent tendency for cases to be particularly numerous in the residential areas adjacent to the railways, yards and terminals in the District of Columbia during a period of years when typhoid was widely prevalent. Epidemiologic investigations of urban typhoid, with particular reference to the location of cases by place of residence, has failed to reveal any definite indication that the incidence of typhoid among persons living in proximity to railroads, terminals and yards is greater than among persons living under conditions otherwise similar but in other parts of the same community.

A report from the Industrial Department of the Metropolitan Life Insurance Company, which was analyzed by Louis I. Dublin, failed to reveal importance for typhoid as a cause of death in various occupational groups, among which are railway enginemen and trainmen and railway yard and track workers. White males engaged in these occupations did not suffer a greater proportionate mortality from this disease than did white males of equivalent ages engaged in other designated occupations.

The review of reports of water borne outbreaks of typhoid occurring prior to 1920 has failed to reveal an instance in which the contamination of the water supply could reasonably be attributed solely or principally to disposal of fecal wastes by railway trains directly into streams in the catchment area or into storage reservoirs, or indirectly into ground waters by flooding or seepage.

Information at present available does not establish the existence of a public health menace resulting from the method of disposal of fecal wastes employed by railways. This does not prove the absence of such a menace. The practice of disposal of fecal wastes along railway rights of way has in the past been a relatively unimportant route of dissemination of the pathogenic micro-organisms which cause the commonly recognized enteric infections. Scattered in this external environment, the chance that any pathogenic fecal micro-organisms will survive until effective contact with a new human host can be made is greatly reduced. Exposed to an external environment, and particularly to the effects of sunlight and drying, typhoid bacilli and other related organisms tend to die off with a rapidity varying with the particular species of micro-organism and the physical, chemical and biologic conditions.

Maxcy concludes that at times and in particular places the disposal of sewage from railway conveyances has been improper in relation to environment and persons and therefore constituted a nuisance. This has not created a hazard which can be measured in terms of increased incidence of enteric disease. The practice has been relatively unimportant in comparison with many other factors in the environment which are responsible for the maintenance and dissemination of enteric infection and disease under the conditions which have existed in the United States. There remains a possibility that there is a danger below this threshold of measurement. Even this theoretical possibility can be reduced to insignificance by technical improvements of disposal which are now well within the realm of practical achievement.

Current Comment

MEDICAL SURVEY OF BITUMINOUS COAL INDUSTRY

In accordance with instructions received from the House of Delegates, the Council on Medical Service and the Council on Industrial Health have kept abreast of developments in the Bituminous Coal Mines Wage Agreement. The survey of health, housing and sanitation in the bituminous coal industry which was stipulated in that agreement has been completed; an abstract appears elsewhere in this issue (page 537). Dr. Walter B. Martin of Virginia, who has acted as chairman of a committee to study the situation, has made the following analysis of the medical survey report:

> The recently released medical survey of the bituminous coal industry is a valuable document. It gives a fair appraisal of the medical situation in the soft coal area. The findings in reference to housing, sanitation and recreational facilities would have their counterpart if a cross section of living conditions were studied in almost any part of the United States. It is of especial interest to note that the prepayment plan of providing medical care in coal mining areas is not considered inherently bad by the survey group. In many places this system has resulted in excellent quality of medical service. Failure in other instances has been due to the human element, particularly to a lack of cooperative effort in local areas on the part of the three groups especially concerned. This report serves to direct attention to existing deficiencies and is a challenge to the physicians of this country. Because of the technical nature of many of the problems involved, good medical leadership is necessary to correct these deficiencies. The shortage of physicians and other skilled personnel, together with the need for expanded physical plants, makes the present solution of some of these problems difficult. They can be solved eventually, however, by friendly cooperation between the miners, the operators and the physicians. Wherever possible, medical service for the miners should be integrated with that of the community.

Admiral Joel T. Boone, who conducted the survey, thus summarizes his observations:

> The Report of the Medical Survey of the Bituminous Coal Industry presents convincing evidence that the serious problem of improving the health of the miner, assuring him of better living conditions, enabling him to provide for his family through his own initiative and efforts, and making him a more responsive and responsible citizen of his community is a solvable problem IF labor, management and the medical profession cooperate and work conjointly with a united interest and sincere devotion to a common cause—the good of large numbers of people and a basic industry. Health is a common concern of all groups. Working together for its promotion can help immeasurably to weld the bonds of human interrelationship.

These statements accord with the established policy of the American Medical Association. No doubt there will be increasing opportunity to make these proposals practically effective.

HEARINGS ON THE TAFT-SMITH-BALL-DONNELL BILL

On May 21 Senator H. Alexander Smith of New Jersey, who is chairman of the Subcommittee on Health of the Committee on Labor and Public Welfare of the United States Senate, opened the hearings on the Taft-Smith-Ball-Donnell bill, known as Senate bill 545, which has been previously described in The Journal editorially and in reports from the Bureau of Legal Medicine and Legislation. On this occasion history repeated itself in reverse order. When the hearings were opened last year on the Wagner-Murray-Dingell bill, Senator Taft appeared and denounced the hearings as organized propaganda in behalf of socialized medicine. This time Senators Murray and Pepper appeared and apparently indulged in recriminations, insisting that the present hearings were propaganda against socialized medicine and that the advocates of the latter were not being given proper time for hearings. Nevertheless, President Truman had sent a message to the Congress a few days previously urging support for nationwide compulsory sickness insurance, and shortly thereafter Senate bill 1320 was introduced, representing the new version of the Wagner-Murray-Dingell bill, this time credited to Senators Murray, Wagner, Pepper, Chavez, Taylor and McGrath. The Journal will publish shortly an analysis of this measure and compare it with previous versions. Among the first to be heard in consideration of Senate bill 545 were Drs. R. L. Sensenich, chairman of the Board of Trustees of the American Medical Association, and E. J. McCormick, chairman of the Council on Medical Service. Condensations of their statements appear elsewhere in this issue (pages 533 and 534).

DIAGNOSIS OF CORONARY THROMBOSIS

Steincrohn[1] called attention in 1940 to a new observation said to be helpful in the diagnosis of coronary thrombosis, namely the rhythm and periodicity of the pain as the most characteristic feature of the syndrome. This periodicity holds true for indefinite attacks as well as for those in which the pain and shock are so prominent that the diagnosis is unquestioned. According to him the pain comes and goes in cycles. Morphine should not be withheld when the patient is first seen in an attack, since the pains will continue to recur and remain recognizable before the morphine exerts its full effect. Steincrohn found this pain syndrome invaluable in ruling out the presence of extracardiac anginas such as acute gallbladder disease, ruptured peptic ulcer, acute pancreatitis, intestinal obstruction, acute pneumothorax and pulmonary embolism or infarct. The cause for the recurring pains is not clear. Theoretically the symptom might be explained on the basis of the changing level of anoxemia, which is dependent on the adjustments which the cardiac circulation is called on to make in the first few hours following the immediate shock of the attack.

ORGANIZATION SECTION

HEARINGS ON S. 545—THE TAFT-SMITH-BALL-DONNELL BILL

Statement of Dr. R. L. Sensenich, Chairman of the Board of Trustees, Before the Hearing May 21, 1947 of the Subcommittee on Health of the Committee on Labor and Public Welfare of the United States Senate.

Dr. Sensenich described the American Medical Association as including 132,659 physicians who are members of the county and state medical societies. The policies of the American Medical Association are determined by the House of Delegates. The members of the House of Delegates, numbering 175, are elected by the respective houses of delegates of the individual states, which in turn are elected by the members of the county medical societies. The Association, thus, is democratic in its organization and in its functions.

He discussed the ten points of its national health program.

It must be recognized that each one of these ten avenues of approach to the problems of health maintenance and necessary treatment reaches directly into each community in the country and directly or indirectly to every individual in that community. The complexity of a problem involving so many factors obviously cannot be adequately dealt with by a single social measure. Likewise it must be admitted that each human being as a mental and physical unit is a more complex structure than any social system that could be devised. So much is dependent on the individual, his capacity, his education, his training, his sense of values and his opportunities that any efforts made in his behalf must take into consideration all of these qualifications.

No social or legal measure can cover this field by any process of compulsion without in the end destroying the very qualities we seek to stimulate and develop in the individual. No social legislation containing those compulsions can be enacted without infringing on the very basic qualities of American freedom. The only social measures compatible with the freedom of our American way of life is that providing opportunity to all and assistance where there is need. Administrators in high position will admit that governmental measures at the top, too far removed from the local community and the individual are, even with the best intent, clumsy and inadequate or restrictive in their final application.

So much is dependent on the education, the interest and the voluntary effort of the individual that elevation of standards and program must be accomplished by local stimulation of effort and cooperation of these individual units in the community. Legislation cannot accomplish those ends. No pattern can be established at the national level that can be practicably applied to the varying conditions in each local community; nor can national regulations deal adequately and fairly in the determination of local need or the application of proper local remedies.

It is therefore evident that effective approach to the problem will rest on the voluntary efforts awakened by stimulation of interest, and development of methods and assistance is demonstrated. It would seem that any legislation directed to this field would be largely concerned with providing financial assistance where need can be demonstrated and the setting up of safeguards to determine equable distribution of that assistance. Contributions from state or local levels should be required in proportion to financial ability. It will be necessary to leave to the local community the administration of local measures without introduction of bureaucratic controls or political interference. . . .

Senate bill 545, introduced by Senator Taft, Senator Smith, Senator Ball and Senator Donnell, more nearly approximates a legislative background for the development of a health program for the American people without destroying or restricting the objectives set forth in the broad national health program of the American Medical Association.

The House of Delegates of the American Medical Association has repeatedly taken action recommending the consolidation of the health activities of the federal government, exclusive of the armed forces and the Veterans Bureau, under a department of health, the head of that department to be a cabinet officer. It was further requested that the cabinet officer shall be a competently trained doctor of medicine experienced in executive administration.

The department of health should not be subservient to any charitable, conservatory or other governmental agency. The American Medical Association opposes the inclusion of the health activities of the nation in a department of health, education and security for the reason that an adequate national health program such as is now in process of development by the American Medical Association could not attain the high objectives sought if it was combined in a department of welfare and security. Evidence to this effect was presented in hearings before the Committee on Expenditures in the Executive Departments, United States Senate, Eightieth Congress. We have copies of the statement to that committee for inclusion in the record of these hearings, if you wish.

There is sufficient reason to maintain that the importance of the health activities is comparable to the importance of other departments and justifies the creation of a department of health of cabinet rank. However, there is equal reason to believe that a national health agency without cabinet rank could better serve the interest of the health of the nation than the inclusion of the health activities with welfare or security, headed by a nonmedical cabinet officer.

In this brief statement, it is impossible to discuss very completely the various features of Senate bill 545. However, certain provisions of the bill should be particularly pointed out, notably the bringing together of all the scattered health activities into a national health agency headed by an outstanding physician; the determination of actual medical needs by requiring state surveys financed from federal funds—this is a highly desirable feature; provisions of grants in aid to states also making some contribution for the extension of medical care to people unable to pay for it; the encouragement of voluntary prepayment plans; the provision for voluntary pay roll deductions of federal employees; periodic examinations of school children, and the provision for encouragement and grants in aid to certain types of research, properly directed.

These provisions of the bill should receive the approval of all those who are interested in a sensible approach to developing methods of extending aid rather than endeavoring to force on the public a preconceived political pattern. It is noteworthy that no effort is made to establish criteria at the national level by which eligibility to a low income classification shall be determined in each local community. Obviously, the section of the country and living costs in proportion to income will have material bearing on that matter.

The appropriation of funds for the support of research in the prevention and control of cancer should be dependent as to the needs for continuation on such cancer research as was formerly under the direction of the Public Health Service. However, the situation might be changed if, as has been proposed, a new committee should be appointed by the President to furnish a central point for coordination of all major cancer research programs. The proposed committee would not be for the purpose of restricting properly organized or equipped effort but rather to prevent the useless expenditures of funds beyond the capacity of facilities or available competent research personnel to carry on that work. Such a committee might well function under this national health agency and might require substantial funds. However, it might be determined that the cancer research conducted under the Public Health Service might be reasonably expanded; but whatever is done should be in proper proportion and well coordinated with other cancer research. Those who are familiar with the research now being conducted and the capacity for expansion have advised of the useless waste of funds if appropriations exceed the amounts that can properly be expanded.

As to the total amount to be authorized annually for a period of five years for the development of the plans for improved health service, it must be recognized that there are no criteria by which the exact amount necessary for this work can be definitely determined. Various figures have been offered along with other legislative proposals. These estimates are frequently predicated on very limited sampling and often suggest that they are influenced by unwarranted enthusiasm for their particular proposal, so widely do they differ from any other reasonable statistical source. The provisions of this bill seem to identify it as being a well planned and sensible approach to meet needs which the whole nation will recognize and approve as a necessary expenditure. The funds to be authorized under this legislation would obviously not be excessive and would vary as needs are determined or as local conditions make continuing aid to communities unnecessary. It is evident that the bill is not the promotion of a colossal plan of governmental regimentation at tremendous cost such as has been proposed.

Placing the responsibility for the administration of these plans at the community level tends to a more personalized community administration and a better integration of the activities under this plan with voluntary agencies and other local social developments. Especially is it important that the personal choice of physician be preserved and that nothing emanating from national government levels be permitted to interfere with these local and personal medical aspects.

The provision for payments to physicians in the areas in which there would be insufficient income from professional services to attract a competent physician will require careful study. The study of these situations may properly be coordinated with the studying and planning for the establishment of facilities as authorized under the Hill-Burton Law. Advisory councils designated by the governors of states may be helpful. Appointments to these positions should be made on the basis of competence and experience with sound medical guidance and not because of political preferences. Especially priorities given to certain areas in the development of facilities and establishment of plans probably will provoke more discussion than any other features of the administration of the act. However, if the personnel of the advisory council is carefully selected and has the respect and confidence of the public, this should not be unusually difficult. The advisory council has no authority other than advisory. The giving of some authority to the council might well be considered.

I do not wish to take the time of the committee in the presentation of technical data which would add nothing to the discussion and might tend to confuse rather than clarify the issues. The American Medical Association stands ready at any time to submit such detailed information as is available which the committee should desire or will provide more detailed reports of medical experience which might be helpful.

In summary, the bill seems to provide plans and means for the interweaving of government and voluntary social and health agencies in such a manner as to permit the broadest variation in response to local needs. The American Medical Association is interested in the whole field of health and is desirous of bringing to every individual the benefits of the highest quality of medical care. It would seem that this bill would provide the legislative basis for meeting the needs of the lower income groups without imposing a huge, expensive system of regimentation with its inevitable destruction of the quality of medical service. The medical profession will continue its efforts toward the development of its National Health Program and will oppose plans that are manifestly against the public interest.

Statement of Dr. Edward J. McCormick, Chairman of the Council on Medical Service

After stating his qualifications Dr. McCormick said:

The Council on Medical Service was created by the House of Delegates of the American Medical Association in 1943 to study and interpret existing and proposed programs pertaining to the economic, social or similar aspects of medical care, to suggest improvements in such programs and to inform the medical profession of its studies. In its task the Council has made every effort to be objective.

We have approached the problem of better health for the American people in proper perspective to the American way of living. Betterment of health is not a single problem. It is not merely a financial problem. It has many aspects and includes many fields of activity. Dr. McCormick traced the development of the A. M. A. National Health Program. He continued:

As physicians we are trained to study, to learn, to know. Improvements in diagnosis and treatment, in surgery, in drugs, are, as they have been for centuries, continually retested, rejected, restricted or extended according to their effect on the health of the people. So too in our Council's work we have instituted studies so that we may learn and know before interpreting or recommending. Our studies have included the voluntary prepayment medical care plans, the cooperative voluntary industrial or commercial carrier plans and compulsory insurance plans. They have also included studies of group practice, contract practice, private practice, clinic practice and other forms of medical organization. Much of the work has been directed to gathering data and general information.

Under title II, part A of Senate bill 545 is a provision for surveys of medical care. The bill authorizes $3,000,000 to assist states in making a statewide inventory of existing medical, hospital and surgical care preparatory to the formulation of a plan for extending such care as contemplated by part B. This is commendable, since it assumes that the first step is the determination of the needs.

Scientific medical care is rendered only by physicians, although often with the aid of nurses, hospital facilities and dentists. That provision in title II, part A, requiring representation of nongovernmental groups or agencies concerned with the provision of services as well as those representing the users is also commendable.

The medical profession has been charged with a desire to maintain a monopoly in medical care programs. Physicians do have a monopoly in the sense that they are the only persons licensed to practice medicine and to provide such services. However, in financing and in the administration of medical programs the medical profession has recognized the assistance that can be supplied by persons experienced in administration and finance. We do insist on the profession's control over medical problems, and in our "standards of acceptance" for voluntary prepayment medical care plans we say "The medical profession should assume responsibility for the medical services included in the benefits; the medical profession is qualified legally and by education to accept responsibility for the character of the medical services rendered."

Part B of the bill authorizes funds to assist the states in providing general health, hospital and medical services for families and individuals in the low income groups. One of the purposes for which these funds may be used is to "provide for the furnishing of such services to such families and individuals by means of payments (in the nature of premiums or partial premiums or reimbursement of expenses or otherwise) by the state, to any voluntary health, medical or hospital insurance fund or other fund, operated not for profit, in behalf of those families and individuals unable to pay the whole cost of such services or insurance therefor."

The American Medical Association favors this method for financing medical and hospital services for the low income groups, provided it is on a voluntary basis. We have many reasons for saying voluntary as opposed to compulsory and will not enter into a discussion of the point here.

Many agencies exist through which a voluntary medical service program can be channeled. The state medical associations and county medical societies have for many years assisted in providing for medical services for the low income groups. The experiences of these organizations with the Federal Emergency Relief Administration plans, the Farm Security Administration plans and local indigent medical care plans provide knowledge for administering such a program. All types, shapes and sizes of plans were given experimental trial during the depression years. More recently the Veterans Administration plans, while not for the medically indigent, have provided medical societies with an opportunity to learn more of the problems involved in administering a medical care program.

Medical societies are organized in every state, the District of Columbia and most of the counties in the United States. They include in their membership a majority of the practicing physicians. They are in a strategic position to determine local conditions, provide for local variances and assess the value and quality of the services. Their participation in programs also places on them an obligation to maintain a high standard of medical practice.

While the American Medical Association favors the method suggested in the bill for meeting the medical needs of low income groups, it questions the feasibility of a "statewide program" as mentioned in number 4 of part A, particularly if the program includes all medical services—unless this statewide program provides for local differences in need, in utilization and so on. This necessity for considering local conditions is brought out in a study of indigent care programs made by the Bureau of Medical Economics of the American Medical Association. This study points out that only twenty of the forty-eight states reported successful operation of a statewide program under the Federal Emergency Relief Administration. The report states "The observation already suggested is confirmed that no nationwide plan of supplying such a personal service as medical care can be satisfactory. To this may now be added the further observation that it is doubtful if statewide plans are practicable in a majority of the states. There are only twenty states in which the plan can be termed 'successful,' even with a liberal use of the word."

At present some thirty-eight statewide Veterans Administration home town medical care programs and ninety-one voluntary prepayment medical care plans are functioning. This seems to contradict the foregoing statements, but there is an explanation and it lies in the scope of services offered by the plans.

The Federal Emergency Relief Administration plans offered general medical care, including home and office calls, to recipients The Veterans Administration and most of the statewide prepayment plans are offering a limited program. Early experiments with plans, other than in Washington and Oregon, showed clearly that the general public preferred a medium priced, partial coverage plan just as experience of automobile collision insurance has shown that the car owners prefer a $25 or $50 deductible policy. As a result, prepayment plans have suited their policies to the needs and demands of the public. Those statewide prepayment plans which do offer a full coverage to subscribers, notably the Washington and Oregon plans, are so constituted as to provide for local—county or area—variations in people, customs, needs, fees and so on This is true also in the actual administration of many of the Veterans Administration programs previously mentioned In other words, needs vary in different localities, and plans are flexible to meet these local needs.

Prepayment medical care plans have been successful on both a statewide and a local basis They have also been successful with both the full coverage and the limited coverage programs. Most of the plans are so organized as to operate in any of the aforementioned categories. Where only local plans exist, they are usually so coordinated as to provide a statewide program

Through the surveys of medical care provided by the bill, decision might well be made, on a local basis, as to the all inclusiveness or comprehensiveness of any given program, this in turn might well be a determining factor as to whether or not there should be a statewide, a local or an area plan

Prepayment plans, as well as medical societies, have worked with governmental agencies in the provision of care for special categories and groups A number of the Veterans Administration programs already mentioned function directly through prepayment medical care plans In at least one state the medical services of the old age pensioners and other special groups are channeled through prepayment medical care plans The statutes under which many of the plans operate specifically provide that contracts be made with the various governmental and nongovernmental organizations and units for the provision of medical care either on the basis of contribution (that is, subscription rate or premium payment) or lump sum for all members of the group involved or on the basis of cost plus a fixed fee. The prepayment plans can cooperate under any or all types of these programs.

Much has been said to belittle the scope of the voluntary prepayment medical care plans, yet the growth in this movement has been phenomenal. In 1942 some fifteen voluntary prepayment medical care plans were listed as approved by medical societies and/or the Blue Cross At present, just a little over five years later, the Council's directory lists ninety-one plans. However, since the Oregon and Washington plans are usually counted as two statewide plans the quotable figure becomes sixty-four. Not only has the number of plans grown rapidly the past few years, but their expansion throughout the United States is even more encouraging The fifteen plans listed in 1942 were operating in ten states, while plans have now been organized in thirty-seven states and the District of Columbia and are in the process of organization in ten additional states.

The growth in the number of medical plans has paralleled that of Blue Cross plans. Slightly more than eight years have been required for the organization of sixty-four medical plans, while in the first eight years of Blue Cross sixty-nine plans developed

Again, as with enrolment, the medical plans expansion throughout the country is comparable to that of Blue Cross In the eight years of the medical plan movement, plans have been begun in thirty-five states which, when added to the early Washington and Oregon plans, make thirty-seven states

In thirteen of the thirty-seven states with plans more than one prepayment plan has developed The effect of local conditions on this development is particularly indicated by the twenty-three plans in the state of Washington, the eight plans in the state of West Virginia, the six plans in New York and the six plans in Oregon

Enrolment in the prepayment plans has increased rapidly in the past two years The reported enrolment Dec 31, 1944 was 1,500,000, Dec 31, 1945, 2,845,000, while on Dec 31, 1946 it was approximately 5,000,000 Since the big growth in the number of plans has taken place during the past two years, it is reasonable to assume that growth of enrolment is just beginning. Eighteen of the plans in operation a year or more on Dec 31, 1946 reported an increase of 100 per cent The highest increase was 1,110.9 per cent, with seven others reporting over 200 per cent Whereas we could point to only one really large plan a year ago, we can point today to five plans with more than 300,000 subscribers and six additional plans with over 100,000 subscribers

Three general types of plans prevail at present. These are cash, indemnity plans, service plans and combinations of the two forms Using sixty-four as the total number of plans now organized, the breakdown as to type is thirty-one indemnity, twenty-eight combination and six service. Any definite trend toward any specific form of plan is not yet apparent. During 1946 and the first part of 1947 twenty plans were organized Of these, seven were indemnity, eleven combination and two service Primarily the determination as to the type of plan rests on the needs and desires of the community in the area in which it is organized The people of our country, according to available evidence, recognize the desirability of prepayment plans for medical care. Many individual citizens still need to be convinced. This means education as to the amount of personal funds which the worker will transfer from nonessential services or goods to protection against the costs of illness. Actually the combination type of plan acts as a service plan for persons in the low income group, so that more than half of the organized plans do operate to protect those in the low income group from excessive charges.

Casual observation might suggest that those plans which offer full coverage are preferable; yet, realization of the tremendous number of problems involved in controlling the abuses on home and office demands for physicians (abuses which would be vastly increased in a compulsory plan) and realization, too, that most workers require help only for the serious illnesses makes evident the desirability that full coverage programs await further experience with plans involving less difficulties. Physicians who have had experience in the illogical and unnecessary demands that can be made on time by those who abuse the plans realize that any general program of this type would be impossible to establish with a good quality of medical care.

Combination plans, as was previously mentioned, are a protection for those in the low income groups against excessive charges These plans provide this protection through utilization of income limits to determine which subscribers are eligible to benefits without additional charges Those below the specified income limits receive the benefits in full; those above the specified income limits may be charged additionally Income limits in these plans vary from $1,500 for a single subscriber to $5,000 for a family. Although many variations are used, the most common seems to be $2,000 for a single subscriber and $3,000 for a family Actually, the importance to the population as a whole of this agreement on the part of physicians to furnish services to a particular income group for a specified fee is overemphasized. Overall studies of existing charges in relation to patients' incomes actually show that the income limit theory is closely adhered to by the profession even in their private practices Yet the idea of income limits does serve a purpose in protecting individuals against unscrupulous practitioners, and obviously it is the charge made by the unscrupulous physician that causes much of the furor concerning the exorbitant cost of medical service Any proposal must differentiate clearly between medical services as provided by physicians and the overall health services which include hospital care, drugs and medication, nonphysician and other services in discussion of this problem

"Basic issues everywhere," it has been said, 'fall into the same pattern, all turning on the contest between those who seek security even if they have to give up freedom and those who think that in the long run the security of the individual will only be possible if freedom is retained" Benjamin Franklin said "They that can give up essential liberty to obtain a little temporary safety deserve neither liberty nor safety" George Washington wrote "He who seeks security through surrender of liberty loses both"

The American people prefer not to be coerced You can reason them into performing in their own way almost any miracle—even winning two world wars. Skeptics have said that voluntary plans for medical care did not succeed in Europe and evolved inevitably into compulsory plans There appears to be some evidence that democracy also is disappearing in Europe.

We need not model our provision of health care for the American people on any failing technic based on European methods of dictatorship and compulsion, we can find a voluntary way compatible with true American democracy.

Just a few weeks ago Winston Churchill said "In my experience of large enterprises, it is often a mistake to try to settle everything at once." With suitable cooperation from a government that wishes to find an answer to a problem rather than to enslave a profession, a technic will evolve that will provide to every American a high quality of medical care

Public Relations

SEEKING SUCCESS IN MEDICAL PUBLIC RELATIONS

LESTER H. PERRY
Harrisburg, Pa.

The first step in the solution of any problem is an analysis of the problem itself, and one must therefore break down this problem of public relations into its component parts before one can begin to plan the program and the organization necessary for the accomplishment of one's objectives.

Public relations is not a pitched battle of propaganda between two determined and unyielding forces. Its results are no longer measured by the number of column inches of publicity appearing in newspapers. On the contrary, some of the finest accomplishments in the field of public relations consist of new solutions to old problems developed and refined in the crucible of self-respecting compromise and cooperation between persons with divergent views. Such results are usually achieved without benefit of newspaper headlines or the blare of human trumpets. As a consequence, it often happens that only the most discerning recognize an outstanding job of public relations when they see one.

This approach, incidentally, does not mean that one must be tepid in one's convictions; it means only that one must be open minded.

The public relations program of a medical society is a composite made up of the following parts:

1. Relations with the individual members of the society.
2. Relations with other medical organizations such as the specialty groups.
3. Relations with allied groups—dentists, hospital administrators, nurses, pharmacists—and with their respective organizations.
4. Relations with voluntary health agencies such as the Cancer Society, the Tuberculosis Association, and the Society for Crippled Children.
5. Relations with governmental agencies—the state departments of health, welfare, public assistance, public instruction and labor and industry, the governor's office, the state board of medical education and licensure, the state legislature and others.
6. Relations with organizations such as the Rotary and Kiwanis clubs, parent-teacher associations, community chests and women's clubs.
7. Relationship with recognized moulders of public opinion—newspaper editors, civic leaders, the clergy, school teachers.
8. Relations between physicians and their individual patients.
9. Relations with that elusive entity commonly referred to as the general public.

This list is not necessarily complete, but it is detailed enough to illustrate that the public relations of a medical society is by no means a simple problem.

In the development of medical public relations, one of the first questions which must be answered relates to the part to be played by the various organizations and individuals concerned. For example, what part of the public relations program of American medicine should be handled by the American Medical Association? By the National Physicians Committee? By the specialty groups? By state medical societies? By county medical societies? By other organizations? By individual doctors of medicine?

From a dollars and cents point of view, American medicine is a big business. The total value of the services rendered by the physicians of this country exceeds the gross income of any of the large corporations with the possible exception of General Motors.

There are no available figures on the total amount spent for public relations by the physicians of this country, but it is evident that this sum has currently reached huge proportions. Notice the difference, however, between the organization of the medical public relations program and that of a corporation such as General Motors. In the case of corporations, their public relations programs are practically always planned, directed, financed and controlled at the national level under the direction of one individual—usually a vice president. By contrast, medical public relations is a hodgepodge of effort that is generally well intentioned and sometimes well executed but almost never coordinated with similar endeavors on the part of other medical organizations.

The very nature of medical service itself makes centralized public relations for the profession both impossible and undesirable. This fact, however, must not retard our efforts at coordination because—without it—duplication and waste will flourish and important segments of the problem will be overlooked.

The American Medical Association is in the process of reorganizing its public relations program. I hope that one of its first objectives will be to determine what phases of the total problem should be handled by the Association itself, by the National Physicians Committee, by specialty groups like the American College of Surgeons and the American College of Physicians, by state and county medical societies and by private practitioners of medicine. This decision will not be easy, nor will the initial determination remain static. Constant vigilance will be needed to make certain that the gears mesh properly, because public relations problems are fluid and the technics necessary to cope with them must be flexible. Changes will have to be made from time to time. This is admittedly a tremendous task, but in my opinion it is a price which the American Medical Association must pay for the medical leadership of this nation. The alternative is chaos in medical public relations and unwarranted expense for the members of the profession who must pay the bill no matter who does the job or how it is done.

A similar problem confronts state and county medical societies. I understand that those in charge of public relations at the Association headquarters plan to provide state and county societies with counsel and aid in the development of state programs. Naturally this cannot be detailed or extensive, but certain patterns can be developed nationally and modified to fit the local landscape.

Every worth while article I have ever read on medical public relations has stressed the importance of the individual practitioner of medicine, but very few of them have explained just how and when and where an individual physician can do a good job of public relations. This must be spelled out in detail by state and county medical societies for their members.

Let us look at medicine's public relations problem from another angle. Public relations is not something apart from the general program of an organization. It cannot be wrapped up in a package and delivered. It is neither a cover for shortcomings nor a substitute for good works. It should not be turned over completely to a single committee or a single individual in the vain hope that, by the use of some magic formula, public reaction can be suddenly transformed. Good public relations, in fact, depends on good works. It cannot exist in a vacuum. Therefore public relations must be built on the program and the accomplishments of the organization.

Successful public relations is always built on a tripod. First there must be positive and constructive policies; second, effective action, and third, adequate interpretation. If any one of these three legs is weak or missing, the public relations program will topple.

Recently I heard a nationally known public relations consultant say that the trouble with physicians is that they are excellent resoluters and motion passers but poor workers at putting their programs across. It is easy, he said, to pass motions galore with no more effort than a full throated "aye," but it is something else again to put ideas on wheels and push them through to completion.

What, for example, are county and state medical societies doing to supply adequate health services and facilities to the rural areas of this country? What are they doing to attract physicians to such areas?

Rural health is only one small part of our problem. Organized medicine has, to be sure, acknowledged its responsibilities in this regard; but until we are able to show concrete results, our rural health program is public relations dynamite. Without results an unfriendly newspaper editor can make us look foolish. And there is little a public relations department can do about the situation until the third leg of the tripod—effective action—is made strong.

Public relations, above all else, must be honest. Reporters and editors are entitled to complete and truthful answers to every reasonable question whether the facts are favorable or unfavorable. Otherwise the confidence of the press is lost and so is one's public relations program.

I can visualize a conscientious employee of a state medical society working full time day after day for a year on the problem of rural health without scratching the surface. By the same token I cannot see how active leadership in this field or in any other field can be achieved by referring the problem to a committee composed of busy practitioners of medicine who must sacrifice a part of their livelihood every day they spend working on the problem unless such a committee is provided with competent assistance to follow through the vast amount of detail which must be handled if concrete results are to be accomplished.

That applies, of course, not only to the problem of rural health but also to every other problem in the solution of which a state medical society desires to exercise active leadership, whether it be sanitation, cancer control, industrial health, mental hygiene or the care of disabled veterans.

In the personnel of medical society committees there exists a remarkable pooling of the best medical talent available. Through their expert services, generously contributed, effective solutions to important health problems can be achieved which would be impossible for employees alone or individual members working separately to approach. Medical society committees are the workshops in which basic policies are forged into concrete programs. I salute the busy practitioners who bring to such committee endeavors a quality of service that could not be purchased at any price. But I think it is utterly unfair to expect that they can solve the important and complex problems referred to them without the assistance of paid employees.

In such a maelstrom of contending social forces as exists today it must be remembered above all else that—regardless of whether their decision is right or wrong—ultimately the voice of the people will prevail. Consequently, in matters of health it behooves organized medicine to guide the public to a sane conclusion. As the initial step in this direction, public confidence must be secured.

The medical profession, however, cannot hope to get very close to the soul of the heterogeneous American public by national or state activities alone. Together, these form an excellent foundation; but the superstructure must be built to fit into the local landscape.

Even the most casual reader of medical history must be impressed by the glorious achievements of the profession in its conquest of baffling scientific problems. He must be particularly thrilled when he discovers, on looking more closely, that the brilliance which shines through almost every page of the history of medicine is but the reflection of an unparalleled devotion to the duties of humanitarian service on the part of countless thousands of individual physicians.

Worth while progress in the field of medical public relations will be achieved once we have applied that traditional devotion to duty which characterized the attack on the scientific front to the problems of social philosophy and human relationships.

230 State Street.

Council on Medical Service

"A MEDICAL SURVEY OF THE BITUMINOUS-COAL INDUSTRY"

The National Bituminous Coal Mine (Krug-Lewis) Agreement of May 1946 provided that a comprehensive survey and study of the hospital and medical facilities, the medical treatment and the sanitary and housing conditions in the coal mining areas be made by the Coal Mines Administrator.

The House of Delegates charged the Council on Medical Service and the Council on Industrial Health with the task of keeping in touch with the situation. In accord with this instruction this report and analysis are presented on the "Medical Survey of the Bituminous-Coal Industry" recently released by Joel T. Boone, Rear Admiral (MC), U. S. Navy, director of the Medical Survey Group.

Fritjof Arestad, M.D., Associate Secretary of the Council on Medical Education and Hospitals, has prepared the analysis of that part of the report having to do with hospital facilities.

THOMAS A. HENDRICKS, *Secretary,*
Council on Medical Service.

CARL PETERSON, M.D., *Secretary,*
Council on Industrial Health.

OPENING STATEMENT

The report entitled "A Medical Survey of the Bituminous-Coal Industry" is unique in that it represents the first nationwide medical survey of an industry conducted under government auspices. The report itself consists of 244 pages plus a 66 page supplement on "the coal miner and his family." It is profusely illustrated with charts and with pictures depicting both the good and the bad features of the coal mine communities.

The following stand out:

1. Facts, information and comments are entirely impartial and are made with every effort to present all sides of the picture or problem.
2. The miner's health and welfare are as good or as poor as the leadership in the community in which he lives.
3. The "mining community" is neither better nor worse than communities in which many other segments of the working population live.
4. The health and welfare of the miners would be definitely improved by applying the accepted standards of industrial medicine to the bituminous coal industry.
5. Improvement of the health and living conditions of the miner can come about only through the cooperation of labor, management, the medical profession and the community itself. No one of these is responsible, no one alone has the remedy.
6. There should be representation from the civilian medical profession on any trusteeship established to provide medical care and hospitalization for the miners and their dependents.

Purpose

The purpose of the survey was to determine the character and scope of improvement which should be made to provide the mine workers of the nation with medical, housing and sanitary facilities conforming to recognized American standards. In interpreting this purpose the director of the survey states that "its objective was to determine broadly the extent, the adequacy and the characteristics of the facilities and services that most directly affect the physical and mental health of the miners and their families."

Extent of Survey

The survey encompassed medical and hospital services and facilities, housing, sanitation, recreation facilities and the use of leisure time by the miner and his family. It traces the origin and development of the coal mining industry in the United States showing how, where and why it spread from coast to coast. In tracing the development, observations are made and factual data presented concerning the character of the communities, the economic conditions of the industry, the mine accident record, mine-labor relations, wage rates, miners' earnings, and the age of the mines themselves.

The survey did not direct itself to the economics of the industry other than historically or to the technology of coal mining. Nor was time available to go into the details of such aspects as the prevalence and incidence of specific diseases and illnesses, the extent and nature of nutritional deficiencies, and other specific details which might be necessary in the actual application of the recommendations made.

Methods Used in Survey

The Secretary of Interior selected Rear Admiral Joel T. Boone (MC), U. S. Navy, to direct the survey, leaving the program entirely in his competent hands. The staff consisted of a headquarters staff of advisers on special matters and a field staff made up of five teams. Each team contained a medical officer, an engineer officer, a welfare and recreation officer and a clerical aide.

The nation was divided into five areas for the survey purposes. Since it was impossible to investigate conditions in all the eight thousand bituminous coal mines or even the 2,350 mines in government possession, a sampling program was adopted. The sampling procedure was based on mine population with a final total of 260 mines agreed on (each of which produces more than 50,000 tons annually). These 260 mines produce 18 per cent of the total coal output of the nation and employ 22 per cent of the miners. They are located in 105 different counties, and these counties in turn are located in the twenty-two leading bituminous coal producing states.

Actual visits were made by the teams to the mines, homes, mine communities and hospitals. A standard recording form was devised so that the teams could gather similar data. Both management and labor were asked to supply representatives to accompany the teams, and all investigations were made in the presence of both.

In addition to the team visits, a questionnaire was prepared and mailed to a large number of mining companies and to all district offices of the United Mine Workers union. The information gathered from these questionnaires was used to verify and corroborate specific items of information obtained by the field teams.

HOUSING AND SANITARY FACILITIES

The study of housing and sanitary facilities brings out all the conditions one would expect to find in a nationwide study of any industrial group of workers: miners owning eight-tube radios but lacking a sanitary toilet, owning a modern washing machine with water drawn from an outside well by pail, getting an ever increasing pay envelop without a comparable improvement of living conditions.

The survey teams visited and studied in detail 2,028 homes in the 260 mine areas and observed without detailed inspection approximately 50,000 dwellings. Fifty-seven per cent of the homes studied were company owned. The background or reasons for the development of both types of dwellings is traced in considerable detail in an effort to lend some sense to the "Tobacco Road" housing found in many mine communities.

Isolation, poor roads, rugged topography, uncertainty of mine return and similar findings are all conditions which were given as affecting the development of mine communities.

The range in extremes with respect to housing, water supplies and sanitary facilities is so wide that the median or average conditions are difficult to determine. While a large majority of miners living in company camps have a standard of living unsatisfactory in view of the levels attained by families throughout the United States in comparable income classes, many examples of excellent company-owned housing are available. The housing and sanitary facilities of the miners who do not live in company towns are generally better than in coal camps. The survey indicates that all three—management, labor and the families—are at fault: management because, having instituted the system, it neglected, with notable exceptions, to fulfil the humanitarian obligations of its dual role of employer-governor; labor because its interest in wages and hours seemingly blinds it to housing and sanitary reforms; and the miner because he tolerates eradicable evils.

PUBLIC HEALTH

In consideration of the emphasis on sanitation facilities in the Krug-Lewis agreement, considerable attention is given to public health administration in coal mining communities. It is contended that proportionate allocation of public health expenditures is not made in these areas. Reasons include imperfect local health department organization, lack of specially qualified personnel, unwillingness to expend funds on privately owned property and lack of an educated demand. Deficiencies exist in all phases of public health administration. Water supply and waste disposal, milk and restaurant sanitation, communicable disease control, child care and school health programs are singled out for special consideration. All elements in the community are at fault, but the report emphasizes that much improvement could occur under effective medical leadership and guidance.

Specific Recommendations Regarding Public Health

1. Mining companies should assure safe water supply, adequate sewage disposal and proper disposal of wastes.

2. Management and labor should act together to promote basic sanitation.

3. New legislation is needed relating to water analysis and adequate water and sewerage systems in relation to new housing projects.

4. Compulsory wash and change house legislation is needed.

5. Adequate financial provision for state and county health units is urged.

6. Local groups should acquaint their representatives in the government about specific public health needs.

7. Extensive and continuous health education programs should be inaugurated.

8. Mine operators should encourage physicians to promote the use of health education and general public health services.

9. A demonstration project in infant and child health should be undertaken.

10. Tuberculosis case finding programs are advocated.

11. Improved reporting, recording and analysis of morbidity and mortality data are essential as a basis for needed medical and public health services.

12. Voluntary health agencies should extend their activities into rural and isolated industrial communities.

INDUSTRIAL MEDICINE

The survey teams found that industrial medicine in its modern application is largely nonexistent in the soft coal mining industry. This anomalous situation prevails in spite of the hazardous nature of the occupation. Only 5 per cent of the mines surveyed maintained any kind of regular medical supervision over workers or the working environment. First aid training and practice, once carried to high degrees of efficiency, have lately deteriorated seriously. Emergency medical care, including transportation and hospitalization, call for a high degree of organization and training and maintenance of auxiliary personnel, since mines are frequently located in relatively isolated regions. Physicians in mining areas are, for the most part, unfamiliar with conditions of the work and in consequence exert little real influence over safety and health programs. This situation is reflected also in low standards of physical examination, job evaluation, placement and absentee analysis, all of which are extremely useful functions of the modern industrial physician. Lack of effective industrial accident and occupational disease control is due in part to deficiencies in scope and administration of workmen's compensation laws. The report indicates that some physicians who receive pay roll deductions for the provision of general medical care still treat industrial disabilities without submitting a separate claim for this service as required under the workmen's compensation laws. Proper use is not being made of agencies designed to rehabilitate disabled civilian workers, and the industry itself has no comprehensive program of restoration, retraining and placement. In regard to industrial medicine, the specific recommendations in the report are as follows:

1. The industry should extend its research activities into all phases of industrial medicine and hygiene and provide consulting services where necessary.

2. Full or part time physicians should be employed to develop and maintain an adequate industrial medical program.

3. Essential elements of an industrial medical service are physical examination, prompt care of industrial accidents, good first aid and emergency facilities, well trained professional personnel, knowledge of working conditions, satisfactory consultant services and the maintenance of adequate records for absentee analysis.

4. The Federal Bureau of Mines should enlarge its scope to include industrial medicine and hygiene.

5. State and local health departments need to extend industrial hygiene services to the coal mining industry.

6. Compulsory rather than elective workmen's compensation acts where they do not now exist are recommended. They should include general coverage for occupational diseases.

7. Proper claims should be made by physicians treating occupational disability in accordance with existing compensation laws.

8. The operators and workers should combine to reestablish first aid training and practice.

9. Medical associations should encourage training in industrial medicine and promote the establishment of special qualifications for practice.

10. Rehabilitation of disabled miners should be supported by the workers and the coal mine operators.

GENERAL MEDICAL SERVICES

A majority of the bituminous coal miners in the United States and their families receive their medical care through a prepayment system by regular deductions from their pay. This system is traditional with them, dating back to the middle of the nineteenth century.

The remoteness of mining communities and other factors that compelled them to provide for housing, water supplies, stores and other necessary provisions also compelled them to attract and retain medical practitioners. As an incentive for physicians to establish themselves in these places, the wage deduction system was instituted to provide funds for an assured minimum income.

The Navy Medical Corps officers assigned to the survey set out to determine the extent of the prepayment system of general medical care in the bituminous coal industry; regional differences, if any, in utilization of the system; the comprehensiveness of the services rendered under the various general prepayment plans; the manner of selecting physicians; the various ways in which plans are administered; the quality of medical care given to miners and their families, and the medical facilities available to miners.

Data were obtained from physicians, mine operators, union officials, medical societies and miners and their dependents at each of the 260 mines selected for the survey.

Extent of Prepaid System

The survey findings show that home and office medical care is provided through some form of prepayment at 155 of the 260 mines surveyed. The remaining 105 mines are generally so located as to allow the employees to live in or near urban communities where private practitioners are available. "Where such (prepayment) plans are in effect, the estimated participation of the employed miners and their families averages more than 95 per cent." These plans are limited primarily to mine employees and their dependents and are not the community-wide type of prepayment plan such as are sponsored at present by medical societies in some thirty-seven states and the District of Columbia.

Regional Differences

Important regional differences were found in the distribution of prepayment plans for general medical care. Plans are more prevalent in areas where housing is or has been provided by mine operators and almost entirely absent in areas where company camps have not been provided. The frequency of prepayment plans is highest in the predominantly rural Southern Appalachians and Rocky Mountains and lowest in the highly industrialized and urbanized Midwestern areas. Prepayment plans are rarely utilized by employees at strip (surface) mining operations that have developed in parts of Oklahoma, Arkansas, Kansas and Missouri.

Charge to Employees

Prepayment is made by pay roll checkoff. The amount ranges from 75 cents to $3 monthly for individuals and from $1.20 to $3 for married employees and dependents, with an average of $1.36 and $2 respectively. No effort is made in the study to correlate the monthly charges with the benefits offered.

Service Provided Under Plans

The usual services offered are office care and necessary attendance on the sick or injured in their homes, provided subscribers live within the company camp or within prescribed geographic limitations. Obstetric care is generally excluded but is sometimes included for an additional fee. Routine immunization is administered without extra cost at 80.3 per cent of the mines.

Dental Services

Dentists are seldom found in typical mining communities.

Contracts and Agreements

To protect the doctor-patient relationship one doctor negotiated separate written agreements with subscribers who authorized the proper pay roll deduction. Physicians furnishing medical care to miners on a pay roll checkoff basis enter into contracts with the company or the local union or both. More than 50 per cent of the agreements were verbal. Where there is a written contract, it is usually entered into between the doctor and the union with the approval of management.

Selection of Physician

In past years management assumed most of the responsibility for selecting a physician. Recently, however, unions have demanded a voice in the appointment of the doctor. Evidence of selection on basis of personal friendships and other nonmedical considerations were found. Management may exert considerable influence on the selection by withholding company-owned office space or living quarters or refusal to make a pay roll deduction for transmittal to a physician whose selection it has not approved. Doctors with contracts under prepayment plans do, in some instances, exercise a voice in selection of additional physicians.

Financial Administration of Plans

Financial administration or supervision of the numerous plans under which prepaid medical services are provided is vested in varying degrees in management, local unions and physicians. Expressed statistically, 127 plans are considered to be controlled primarily by the contract physician, 14 are company sponsored in providing medical facilities and salaried physicians, 8 are controlled by the union and 5 are administered by a joint commission.

Labor's Concern in Medical Care

In recent years, problems associated with the administration of prepaid medical services have resulted in the interjection of certain pertinent provisions in the labor contracts between coal operators and the union.

Patients' Choice of Physician

Unless he wishes to pay extra to obtain the services of a doctor who is not associated with the prepayment plan, the miner must accept the services of the contract physician. In some places the contract physician is the only doctor available. Where two or more physicians are practicing at some mines or groups of mines, the participant in the plan is usually assigned to only one of them. If several of the independent prepayment plans could be grouped, the participants would then be enabled to have a choice of doctor, limited only by the size of the group. Furthermore, he would have a physician to call on in an emergency if the physician of his choice was away. Doctors likewise would be able to rotate their practice when desirable.

Facilities for Treatment

At only 17 of the 260 mines surveyed have the companies erected and equipped excellent dispensaries to be utilized for industrial medicine and ordinary medical care of miners and dependents. Generally the company doctors' offices are in small frame buildings for which management charges nominal rent. The equipment of such offices ranges from that carried in a practitioner's bag to that found in a modern up to date office with sanitary features and modern physical therapy equipment. These offices are equipped by the doctor rather than by the company. "It is axiomatic that the extent of utilization and value of medical care facilities . . . depends on the availability and competence of professional personnel. Conversely, it is also true that the availability of good doctors frequently depends on the existence in a community of suitable physical facilities."

Attitude Toward Prepayment

The quality of medical facilities at the mines, the limited choice of physicians, the ways in which physicians are selected and the exclusions under the prevailing prepayment plans have all given rise to dissatisfaction by management, by labor, by physicians and by patients. Although the groups acknowledge the need for improvements, the concept of a prepayment system for medical care is acceptable to all parties, and abandonment would not only be resisted but would be undesirable.

It is indisputable that many physicians have been attracted to unprepossessing areas by a guaranteed minimum income each month. This economic advantage is responsible in a large measure for the fact that mining communities are as well supplied with physicians as they are. Under any revision of the system, provision should be made for a subsidy, retainer or minimum salary or other suitable method of payment for physicians who are willing to practice in such relatively isolated localities, to which otherwise they might not be attracted.

"Many of the mine physicians participating in contract practice believe that prepayment by pay roll checkoff is essential to the provision of medical care in most mining communities."

There are many advantages to the miners inherent in any prepayment "insurance" system of medical care where the risk is spread over a large group of people. Economic burdens are lightened for the individual through the distribution of costs and the individual protected against large outlays of funds in times of medical emergency.

Most of the causes of dissatisfaction hindering operation will not be eliminated until prepayment funds are administered by a representative body so constituted as to be above suspicion of partiality to the mine operator, the physician, the union or the miner. The objective should be to provide maximum service to the individual patient at the lowest cost consistent with (*a*) adequate remuneration to physicians for services rendered, (*b*) expansion and improvement of medical facilities and (*c*) the furthering of medical science.

Improvement in the administration of medical prepayment plans will be accompanied by the formulation of equitable written contracts clearly defining privileges and limitations. The subscriber should know what he is buying with his prepayments. A desirable requisite is freedom of choice of physician from among all legally qualified doctors who desire to participate, physicians should be paid from a fund centrally administered by a nonprofit association on the basis of specific services performed, and, to prevent abuses, consideration should be given to proposals that the subscriber should pay some moderate portion of the first cost of each illness.

An urgent need exists for the medical profession in each of the coal mining states to develop, in cooperation with management and labor, actuarially sound prepayment plans which will furnish the maximum of medical service coverage at the lowest cost consistent with continued improvement of services and facilities and opportunity for future scientific progress.

The development of such plans by the medical profession with the United Mine Workers of America and mine operators would contribute to the solution of many health problems of the people in the bituminous coal mining industry.

HOSPITALIZATION

Although the practice of prepayment of hospitalization is firmly established in the bituminous coal industry, there is great variation among the local plans. This situation, however, is no different from that of other prepayment plans throughout the country. Prepayment plans sponsored by medical organizations, Blue Cross and private insurance companies differ throughout the country. Such differences are necessary to accommodate local needs and desires in the areas served.

The various agencies administering these plans and a brief description follow:

1. Hospital Administered Plans: These plans are administered by what are known as "list" or contract hospitals. These hospitals have agreed to render certain services to beneficiaries. Such services are paid for by a "checkoff" from each miner's pay. The deductions are remitted in total to the contracting hospitals.

2. Nonprofit Associations: In several areas there are agencies which are incorporated on a legal nonprofit basis for the purpose of providing hospitalization to subscribers. These agencies make agreements with "participating" hospitals whereby such hospitals agree to provide specified hospital services to beneficiaries.

3. Mutual Benefit Associations: These associations are normally formed by the employees. In many instances the benefits go beyond providing hospitalization to beneficiaries and include cash indemnities for burial expenses, for disabilities resulting from accidents or illnesses and for support of survivors in case of death.

4. Union Administered Plans: The survey teams found such plans in all areas, but they predominated in the West. Union plans are no more specific in their provisions regarding benefits to subscribers than are other plans.

5. Employer Administered Plans: These plans are administered solely by the employers, usually by means of making company owned or operated hospital facilities available to the beneficiaries.

6. Physician Administered Plans: Such plans do not differ materially from the hospital administered plans. In most instances the physicians administering these plans own the hospitals with which contracts have been made or they are members of the hospital staffs.

7. Hospital-Operator-Union Administered Plans: Only one such plan was observed in the survey. It is operated by a commission composed of representatives of the hospital, management and employees of coal companies. This was reported to be the outgrowth of one originally devised by the hospital to care for indigent patients and persons with low incomes.

8. Indemnity Plans: Seven per cent of the plans studied were indemnity type group insurance contracts carried with private insurance companies.

Recommendations on Medical and Hospital Plans

In establishing any broad system to provide comprehensive medical and hospital care for miners and their dependents, the survey suggests that serious consideration be given to the following:

1. Plans should be administered on a sound actuarial basis.
2. Plans should cover as wide an area as is practicable and feasible.
3. Each subscriber should know exactly what he is paying for and to what he is entitled.
4. Eligibility to subscribe to prepayment plans should not be limited to a single occupational group.
5. Scope of plans should be broad enough to permit participation by employer, company officials and supervisory personnel.
6. Each plan should make sound provisions for continuing benefits during periods of cessation of the income of participants.
7. Subscribers should be permitted to continue to participate following termination or transfer of employment.
8. Subscribers should be allowed free choice among an adequate number of hospitals and physicians who are willing to participate.
9. Funds should be sufficient to assure an adequate panel of participating physicians.
10. The plan should allow maximum professional competition compatible with high quality and reasonable economy.
11. Plans should seek the endorsement of the medical profession.
12. Checks should be included within the plans to prevent unnecessary demands by malingering patients.
13. Administration should not result in domination or coercion of physicians.
14. Responsibility for maintaining standards of medical care should be retained by the medical profession.
15. Provisions should be made for adjudicating grievances that may arise in the administration of the plan.

HOSPITAL FACILITIES

Included in the report is a survey of 153 hospitals closely associated with the bituminous coal industry. These institutions were studied from both a quantitative and a qualitative point of view, utilizing mainly such factors as size, distribution, ownership or control, surgical and obstetric facilities, x-ray and laboratory service and the availability of medical, nursing and technical personnel. Of the hospitals surveyed, 75 per cent had a capacity of less than 150 beds, indicating that most of the miners depend on small or medium size hospitals located close to their homes.

All the hospitals included in the report rendered the usual medical and surgical services, and all but two provided facilities for obstetric care. Although many hospitals were well organized and well equipped, a considerable number exhibited deficiencies in various departments, particularly in the areas where small hospitals predominated. In relation to surgery, for example, it was reported that 30 per cent of the hospitals did not have adequate facilities, but in this connection it should be noted that the standard of comparison had been placed at a minimum of two operating rooms for all hospitals below 150 beds. Sixteen per cent of the hospitals surveyed did not maintain separate delivery rooms, 40 per cent lacked a labor room, and approximately 10 per cent did not have a nursery for the segregation and care of newborn infants. Nearly all the hospitals, however, had facilities for x-ray and laboratory work.

The nationwide shortage of nursing personnel was also reflected in the hospitals of the coal areas, where over 60 per cent of the institutions failed to meet the established index of 2 beds per nurse. Laboratory technicians were not employed in 30 per cent of the small hospitals and in 10 per cent of the hospitals of medium size. It was also reported that 30 to 50 per cent of the hospitals did not list on their staff any physicians who specialized in surgery, internal medicine or obstetrics. A full evaluation of these services, however, would no doubt require a further study of the qualifications, training and experience of the individual staff physicians.

The report recommends that hospital facilities in the bituminous coal mining areas be increased in size and improved in quality, that multiple small hospitals be consolidated into nonprofit associations whenever possible so that they may benefit under the Hospital Survey and Construction Act, and that small hospitals which cannot be consolidated affiliate themselves with larger institutions or limit their services to special phases of hospital work. It was further urged that increased attention be given to the specialties, that young physicians be induced to enter the coal areas under conditions that will permit them to advance professionally and financially, that hospitals extend their attending privileges to local physicians, that standards of administration, facilities and practice be established in accordance with the principles set forth by the American Medical Association, the American Hospital Association and other agencies, and that hospitals be licensed and also inspected at regular intervals. It was likewise urged that the United Mine Workers of America together with coal operators aid in the development of leadership in the establishment and improvement of community hospital facilities under the Hospital Construction Act.

The report calls attention to deficiencies in hospital facilities and services and indicates that "such attitudes appear to be most prevalent where the present system of contract hospitalization—a system that stifles competition on the basis of quality of service—is dominant." It states further that, "in the interest of proper medical care, the medical profession should closely scrutinize the present methods of practice in the coal mining areas and make modifications wherever necessary to provide adequate diagnostic services and treatment facilities, and enough fully qualified physicians to handle the needs of the regions."

OFF-THE-JOB LIVING

In the survey, off-the-job living is considered to include all the things the individual chooses to do in his own time for gratification of the doing.

What an individual does in his own time has a great deal to do with shaping his personality and coloring his attitudes. "This is where recreation comes in, for recreation is a means of satisfying human hungers for self expression and creativeness, for belonging to the group and being wanted, and for recognition, competition and adventure."

The circumstances in many coal mining areas limit the activities of private and public agencies as well as those of commercial firms, some of these inhibiting circumstances being that (1) areas are sparsely settled, (2) working time and earnings of inhabitants are irregular and undependable, (3) the land is owned or leased by mine operators and not generally available for lease or purchase, (4) many communities are unincorporated and there are no public bodies to provide recreational opportunities for residents, and (5) the proper use of leisure time depends on leadership as well as on facilities and programs.

In a great measure the people in coal mining areas depend on four sources—management, labor, the school and the church—for their recreational activities.

Leadership is of vital necessity in stimulating the major interests of the people, and instances were discovered in which recreational facilities that had been provided and installed were deteriorating rapidly from nonuse. Lack of adequate and interested leadership was given as the cause.

Recreational facilities are in direct ratio with other facilities available in individual camps and communities. They are better and more readily available in the larger incorporated communities with diversified classes of people, poorer in incorporated communities comprising mining families and workers in professions and trades different on mining and poorest in company owned camps and unincorporated communities made up almost solely of mining people. "These facts point out that community organization is needed to provide the basic needs for recreational facilities and comprehensive leisure time programs."

CENTENNIAL BROADCASTS FROM ATLANTIC CITY

Here again the Bureau of Health Education announces the following broadcasts connected with the Centennial Celebration of the American Medical Association at Atlantic City:

Saturday, June 7, 4:30 p. m., Eastern Daylight Time, Columbia Broadcasting System and associated stations: "Science Service Program." R. L. Sensenich, Chairman of the Board of Trustees, guest speaker. Topic, "Medicine's Centennial Year."

Saturday, June 7. "Doctors—Then and Now," Nevada and Northern California, speaker Lawrence Parsons, M.D., representing Nevada and California Medical Associations; N. B. C. and affiliated stations, 4:30 to 5 p. m., Eastern Daylight Time.

Saturday, June 7. "Generations of Doctors" (tentative title), a fantasy story of the doctor of 1847 in contrast with his descendant, a doctor of 1947, dramatized with music; Columbia Broadcasting System and affiliated stations, 10:30 to 11 p. m., Eastern Daylight Time.

Sunday, June 8. Speakers from the Centennial religious observance, Msgr. Fulton J. Sheen, Rabbi Joshua Loth Liebman and Dr. Ralph C. Hutchison, President of Lafayette College; N. B. C. and affiliated stations, 11 to 11:30 a. m., Eastern Daylight Time.

Monday, June 9. Official opening of the Scientific Exhibit, Dr. Morris Fishbein, Editor of The Journal, and Dr. Harrison H. Shoulders, President of the American Medical Association; American Broadcasting System and affiliated stations, 4:15 to 4:30 p. m., Eastern Daylight Time.

Monday, June 9. "Stephen Graham, Family Doctor": this Mutual network broadcast, usually originating from New York, will be originated from the American Room at the Hotel Traymore as the entertainment feature for the annual dinner tendered the House of Delegates and officers of the American Medical Association by the local medical profession. The entire production will be moved from New York as a demonstration to the delegates and as a special event commemorating the Centennial of the American Medical Association. The topic will be "Medical Service in Rural Areas." The special script will be written by Willys Cooper and produced by Wynn Wright. The program is under the general supervision of Dr. W. W. Bauer and Harriet Hester.

Wednesday, June 11. Address by Dr. Edward L. Bortz: Columbia Broadcasting System, 6:15 to 6:30 p. m., Eastern Daylight Time. Topic: "Looking Forward from A. M. A. Centennial."

Friday, June 13.—*Interview: Dr. Edward L. Bortz,* President of the American Medical Association; interviewed by Harriet Hester, Mutual Broadcasting System and affiliated stations, 10:30 to 10:45 a. m., Eastern Daylight Time. Topic: "One Hundred Years of American Medicine."

Saturday, June 14. "Doctors—Then and Now"; closing program of the series entitled "American Medical Cavalcade," summarized by Dr. W. W. Bauer; N. B. C. and affiliated stations, 4:30 to 5 p. m., Eastern Daylight Time.

In addition to the Monday night Mutual broadcast of the "Stephen Graham, Family Doctor" show, the speeches by Drs. Fishbein and Shoulders on the American Broadcasting System, and the speeches of Dr. Bortz on the Columbia Broadcasting System and the Mutual Broadcasting System will originate from Atlantic City; "Doctors—Then and Now" on N. B. C. will originate both Saturdays from Chicago; "Generations of Doctors" on C. B. S. will originate from New York.

Coming Medical Meetings

American Medical Association, Atlantic City, June 9-13. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American College of Allergists, Atlantic City, Hotel Senator, June 6-8. Dr. Fred W. Wittich, 401 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Chest Physicians, Atlantic City, Ambassador Hotel, June 5-8. Mr. Murray Kornfeld, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Radiology, Atlantic City, Haddon Hall, June 7-8. Mr. Mac F. Cahal, 20 N. Wacker Drive, Chicago 6, Executive Secretary.

American Diabetes Association, Atlantic City, Chalfonte-Haddon Hall, June 7-8. Dr. Cecil Striker, 1019 Provident Bank Bldg., Cincinnati 2, Secretary.

American Medical Women's Association, Atlantic City, Hotel Claridge, June 7-8. Dr. Helen F. Schrack, 216 N. Fifth St., Camden, N J., Secretary.

American Neisserian Medical Society, Atlantic City, Marlborough-Blenheim Hotel, June 8. Dr. William L. Fleming, 750 Harrison Ave., Boston, Secretary.

American Neurological Association, Atlantic City, Marlborough Blenheim Hotel, June 16-18. Dr. Walter O. Klingman, 195 Ft. Washington Ave., New York 32, Secretary.

American Physiotherapy Association, Pacific Grove, Calif., July 6-12. Miss Mildred Elson, 1790 Broadway, New York 19, Secretary.

American Proctologic Society, Atlantic City, June 7-8. Dr. Harry E. Bacon, 2031 Locust St., Philadelphia 3, Secretary.

American Radium Society, Atlantic City, June 8. Dr. Hugh F. Hare, 605 Commonwealth Ave., Boston 15, Secretary.

American Society for the Study of Sterility, Atlantic City, Hotel Strand, June 7-8. Dr. John O. Haman, 490 Post St., San Francisco 2, Secretary.

American Society of Electroencephalography, Atlantic City, Marlborough Blenheim Hotel, June 13-14. Dr. Robert S Schwab, Massachusetts General Hospital, Boston 14, Secretary.

American Urological Association, Buffalo, N. Y., Hotel Statler, June 30-July 3. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Idaho State Medical Association, Sun Valley, June 16-19. Dr. William B. Handford, Caldwell, Secretary.

Maine Medical Association, York Harbor, Marshall House, June 22-24 Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Minnesota State Medical Association, Duluth, June 30-July 2. Dr. B. B Souster, Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Montana, Medical Association of, Missoula, June 26-28. Dr. H. T. Caraway, 115 N. 28th St., Billings, Secretary.

National Tuberculosis Association, San Francisco, June 16-19. Dr. F. D. Hopkins, 1790 Broadway, New York 19, Executive Secretary.

New Hampshire Medical Society, Portsmouth, Hotel Wentworth, June 19-20. Dr. Carleton R. Metcalf, 5 South State Street, Concord, Secretary.

South Dakota State Medical Association, Rapid City, May 31-June 3. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

Wyoming State Medical Society, Sheridan, June 23-25. Dr. George E. Baker, 226 E. 2d St., Casper, Secretary.

Washington Letter

(From a Special Correspondent)

June 4, 1947.

Republicans Reject Truman Appeal for Action on Federal Health Insurance

Senator Robert Taft of Ohio, president of the Republican Policy Committee, announced that the Republican controlled Senate had no place on its 1947 legislative calendar for the "long and bitter battle" that would ensue if efforts were made to pass a federal health bill as advocated by President Truman. Mr. Taft added that the Labor Committee which he heads will hold hearings on health needs shortly, although a bill will not be taken up this year. He has already launched a bill to expand medical and dental care through federal aid to states. Republicans opposed the President's suggestion of a health and disability insurance program on the ground that it would involve nationalized medical service. Senator Murray, Democrat of Montana, co-author of the Murray-Wagner-Dingell bill, has since introduced a bill to carry out most of the suggestions made by President Truman in his message to Congress.

Senate Endorses Bill to Create Agency on Scientific Research

The Senate voted 79 to 8 for the creation of a new government agency, a National Science Foundation, to conduct basic research in biologic and other scientific fields. The measure has an uncertain fate in store in the House of Representatives. An amendment by Senator Magnuson, Democrat of Washington, was passed by a 42 to 41 vote with 5 Republicans joining 37 Democrats, providing for a $15,000 a year director, appointed by the President, to execute all foundation policies. Also passed was an amendment providing that 25 per cent of funds later appropriated are to be allocated to the states for distribution. The original bill would liquidate the Office of Scientific Research and Development as of June 30 and would absorb the National Roster of Scientific and Professional Personnel, now in the Labor Department.

Senate Votes Special Commissions on Remedies for Cancer and Heart Disease

In voting passage of the National Science Foundation bill the Senate also approved an amendment by voice vote authorizing the proposed foundation to set up cancer and heart disease commissions. Each commission would be asked to survey public and private research in the field and recommend research programs to be carried out through the foundation. In the House, Representative Dirksen, Republican of Illinois, has asked the House Appropriations Committee to give the Atomic Energy Commission $25,000,000 to fight cancer. He declared that it has been estimated that 17 million people now living will die of cancer.

Captain Nellie Jane DeWitt Heads Navy Nurse Corps

Navy Secretary Forrestal announced on the thirty-ninth anniversary of the Navy Nurse Corps the appointment of Capt. Nellie Jane DeWitt as new director of the corps.

Official Notes

QUESTIONNARIE TO MEDICAL OFFICERS

The analysis of the 26,000 replies to the 50,000 questionnaires sent by the Committee on National Emergency Medical Service to discharged medical officers has been completed in time for presentation to the House of Delegates at Atlantic City. A copy of this report of approximately thirty-five pages will be mailed to any discharged medical officer who requests a copy from the Bureau of Medical Economic Research, Chicago.

The analysis of the questionnaire on Medical Care of Civilians During World War II appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION May 24, pp. 369-374, and an editorial appears on page 366.

Medical Legislation

MEDICAL BILLS IN CONGRESS

National Science Foundation

A bill providing for the establishment of a **National Science Foundation**, S. 526, has passed the Senate. In addition to providing for five divisions within the foundation, including a Division of Medical Research, the bill directs the foundation to establish *(a)* a special Commission on Cancer Research, *(b)* a special Commission on Heart and Intravascular Diseases and *(c)* such other special commissions as the foundation may from time to time deem necessary. Each special commission will have authority to make a full and adequate survey of research, both public and private, being carried on in its field, to formulate and recommend to the National Science Foundation an overall research program in its field and constantly to review the manner in which such programs are being carried out.

Army and Navy Medical Departments

The bill proposing to **revise the Medical Department** of the Army and the Medical Department of the Navy, H. R. 3215, has been reported to the House with the recommendation that it pass. This legislation, among other things, would establish in the Medical Departments of the Army and Navy a Medical Service Corps consisting of the pharmacy, Supply and Administrative Section, the Medical Allied Sciences Section, the Optometry Section and such other sections as the Secretary of War or the Secretary of Navy, as the case may be, may deem necessary.

Compulsory Sickness Insurance

President Truman on May 19 transmitted to the Congress a special message containing his recommendations for the development and enactment of **national health and disability insurance programs.** He recommended (1) adequate public health services, including an expanded maternal and child health program, (2) additional medical research and medical education, (3) more hospitals and more doctors in all areas of the country where they are needed, (4) insurance against the cost of medical care and (5) protection against loss of earnings during illness.

The day following the transmission of this special message, a new version of the Wagner-Murray-Dingell bill was introduced in the Senate as S. 1320 by Senators Murray, Wagner, Pepper, Chavez, Taylor and McGrath Companion bills were introduced in the House by Representative Dingell as H. R. 3548 and by Representative Celler as H. R. 3579.

The 1947 version proposes to remove the administration of the legislation on a federal level from the United States Public Health Service and place it in a board of five persons established as a part of the Federal Security Agency. The members of this board, it is proposed, will be on a full time salary and three of them would be appointed by the President, one a physician, with the approval of the Senate. The Surgeon General of the United States Public Health Service and the Commissioner of Social Security will be the other two members, ex officio. Detailed provisions have been added in an effort to give recognition to voluntary plans, additional groups to be covered have been added and special provisions included for the supplying of services to rural areas. In broad outline, the new bill does not depart from the philosophy of the earlier bill and retains the compulsory features that characterized its predecessor.

Medical Research Agencies

A bill introduced by Representative Hand, New Jersey, as H. R. 3661 proposes to establish an independent agency of the government to be known as the **Medical Research Agency** to initiate, conduct and support scientific research with respect to the cause and cure of cancer, rheumatic fever, Bright's disease, diabetes, diseases of the heart and circulation, and other major diseases of mankind, and to investigate the cause and spread of contagious or infectious diseases, including malaria. To enable the agency to organize and to commence to carry out its powers and duties an appropriation of $5,000,000 will be authorized. Thereafter, such appropriations will be made available annually as the Congress may authorize.

Miscellaneous

H. R. 1714 has been reported to the House, proposing **to exclude from the Classification Act** and other laws relating to compensation and benefits of federal employees, student nurses, medical or dental interns, residents-in-training, student dietitians, student physical therapists and student occupational therapists, assigned or attached to a hospital, clinic or medical or dental laboratory operated by any department, agency or instrumentality of the federal government or by the District of Columbia and any other student-employees, assigned or attached to any such hospital, clinic or laboratory primarily for training purposes, who may be designated by the head of such department, agency or instrumentality, or by the Commissioners of the District of Columbia, as the case may be, with the approval of the Civil Service Commission.

A bill introduced by Representative LeCompte, Iowa, as H. R. 2815, **would provide hospitalization** for persons who (1) have served on active duty in time of peace in any branch of the armed forces of the United States and have been honorably discharged from such service; (2) are suffering from any disability, disease or defect and are, in the judgment of the Administrator of Veterans' Affairs, in need of hospitalization or domiciliary care; and (3) swear that they are unable to defray the expenses of the necessary hospitalization or domiciliary care.

In providing for **additional tax reductions** from gross income, a bill introduced by Representative Keating, New York, as H R 2850 would, among other things, permit the deduction of all necessary expenses incurred by professional persons "in taking required instructions in connection with his work."

A bill introduced by Representative Rogers, Massachusetts, by request, as H. R. 3599, would direct the Administrator of Veteran's Affairs to provide **complete medical care** for the widows and children of persons who died as a result of service in the armed forces of the United States *in time of war.*

H R. 3336, introduced by Representative Brehm, Ohio, proposes that the Medical Department of the United States Army shall be reorganized so as to provide for *greater autonomy of* **the dental service.**

A bill introduced by Representative Morrison, Louisiana, as H R 3443 would amend existing law to eliminate the requirement that a veteran, in order to receive medical or hospital care for a non-service connected disability, must declare that he is **financially unable** to defray the expense of such care.

A bill introduced by Representative Buck, New York, as H R 3073 would provide medical advice and outpatient treatment by the United States Public Health Service to the **widows and minor children** of certain deceased personnel of the Regular Coast Guard and of the United States Coast Guard Reserve, of the United States Coast and Geodetic Survey and commissioned officers of the regular corps of the Public Health Service and of the Reserve Corps when on active duty or when retired for disability.

The Federal Food, Drug and Cosmetic Act would be amended by a *bill introduced by Senator White, by request, as S 1190, so as to* provide for **seizure of foods, drugs,** devices and cosmetics which become adulterated or misbranded while held for sale *after* shipment in interstate commerce.

STATE LEGISLATION

California

Bills Introduced.—A 2307 proposes that **dogs and cats** may be used for studies or investigations requiring the cutting, crushing or burning of tissues or the administration of drugs, biologicals or chemical products only in institutions or laboratories approved by the state department of public health. The proposal then authorizes the state department of public health to grant written approvals for such purposes to universities and colleges in the state maintaining medical, dental, veterinarian or agricultural schools or scientific research or experimental departments *and to public or private laboratories* that are licensed or approved by the National Institute of Health. The approval, when granted would remain valid and in force and effect until surrendered. A 2681, to amend the law relating to the **practice of chiropractic,** proposes to define chiropractic as consisting of "any or all acts essential to the application of chiropractic principles. Said acts are directed chiefly to the proposition of *adjusting vertebral subluxations for the purpose* of reducing obstructive *pressure on nerves, where they lie in inter*vertebral foramina, or pressure on the spinal cord." The proposal would further define the terms "impingement, subluxation and adjustment" as follows: "Impingement is the state of any nerve, or the tissues of the spinal cord or brain, on which there is sufficient pressure to obstruct the transmission of nervous energy. Subluxation is any relation of contiguous vertebrae, of the first cervical vertebra and the occipital bone, of the fifth lumbar vertebra and sacrum or of any osseous articulation in which nerves may be subjected to obstructive pressure. Chiropractic adjustment is the voluntary and specific reestablishment of *proper vertebral relationship for the purpose of* relieving obstructive pressure on spinal nerves or the spinal cord." S 1059, to amend the law relating to offenses against the chapter on medicine and surgery, proposes that no person who does not hold at the time thereof an unrevoked and unsuspended certificate as a physician and surgeon shall make a ***postmortem examination*** *or perform an autopsy on the remains* of a deceased person.

Bills Enacted.—S 353, which has become chapter 327 of the Laws of 1947, is a **hospital survey and construction act** requiring a state wide survey of hospital facilities and the formulating of a plan for the *construction of additional* needed facilities, as well as the establishment of an advisory hospital council. The survey is to be administered by the state department of public health, which department is appointed as the state agency to accept money received from the federal government for state assistance in either *survey or construction programs.* S 1070, which has become chapter 309 of the Laws of 1947, amends the business and professions code by making it an act of unprofessional conduct for a practitioner to be **convicted of a violation of the narcotic or dangerous drugs** statutes of the state. S 1071, which has become chapter 308 of the Laws of 1947, amends the business and professions code by making it an act of **unprofessional conduct** for a practitioner to administer to himself cocaine, opium, morphine, codeine, heroin, alpha eucaine, beta eucaine, *chloral hydrate, paraldehyde* or barbituric acid, any of the narcotics or alcoholic beverages to an extent which is injurious to his practice.

Colorado

Bill Enacted.—S. 524, which was approved May 16, 1947, amends the law relating to **venereal diseases** by providing, among other things, that no person other than a *licensed physician* shall treat or prescribe for a case of venereal disease. It also provides that no person shall sell or dispense a *drug, medicine,* remedy or preparation for the treatment, relief or cure of such a disease except on the original written prescription of a duly licensed physician, which prescription shall bear the name and address of the prescribing physician and the name of the municipality or health district *in which the patient resides.*

Connecticut

Bills Enacted.—H. 922, which *has become public act 104 of the Acts* of 1947, relating to the **practice of naturopathy,** suspends the provisions of the naturopathic practice act relating to licensure without examination until the adjournment of the 1947 session of the general assembly. S 15, which has become Special Act 120 of the Acts of 1947, amends the charter of the **Connecticut Medical Society** by changing the name of the society from "The Connecticut State Medical Society" to "The Connecticut Medical Society" *and by eliminating* the limit of $100,000 on the value of real and personal estate which the society may purchase, receive, hold or convey.

Florida

Bill Introduced.—H. 312, to amend the law relating to the membership **of the state board of health,** proposes to authorize a person other than a doctor of medicine to be a *member thereof, that is,* "a licensed practitioner under the laws of the state of Florida of one of the healing arts for the treatment of human ills other than a doctor of medicine."

Bill Passed.—S. 710, which passed the senate May 21, proposes to authorize **colleges in the state of Florida** which are empowered to teach anatomy to obtain the bodies of unclaimed persons who die in the county poor farms and county hospitals for the purpose of medical, surgical or anatomic study or dissection.

Illinois

Bill Introduced.—S. 414 proposes the creation within the department of labor of a **board of industrial hygiene and safety.**

Michigan

Bill Introduced.—H. 466, relating to **absences from school** of children *who are physically unable to attend, proposes to authorize the attendance* officer to secure a written statement from a physician having the qualifications prescribed by the medical practice act or the osteopathic practice act certifying that such child is physically unable to attend school.

Bill Enacted.—H. 204, which has become public act 106 of the Acts of 1947, is a licensing law for **privately owned hospitals,** homes and institutions for the care and treatment of mentally diseased persons.

Minnesota

Bill Enacted.—S. 966, which has become chapter 240 of the Laws of 1947, provides, among other things, that no person shall act as **a superintendent or administrative head** of a hospital or sanatorium without first registering with the state board of health.

Ohio

Bill Introduced.—H. R. 75 proposes the creation of a **committee to make inquiries** and investigations into any and all matters pertaining to any of the state examining boards, including the medical examining board.

Bill Passed.—H. 295, which passed the house May 21, proposes to authorize the use in court of evidence of **the amount of alcohol** in a person's blood taken within two hours of the time after he is arrested as shown by a *chemical analysis* of his blood, urine, breath or saliva. This proposal would apply to the trial of any action or proceeding arising out of acts alleged to have been committed by any person arrested for operating a motor vehicle or motorcycle while in an intoxicated condition.

Oklahoma

Bill Enacted.—H 278, which was approved May 22, 1947, makes *it a misdemeanor for any person to use* ***the word "doctor"*** *or to hold* himself out as qualifying to engage in the practice of any of the healing arts without holding an unrevoked license or certificate issued by the laws of the state authorizing the person to practice the healing art covered by the license.

Pennsylvania

Bills Introduced.—S. 745 proposes to **exempt from taxation** the properties of charitable hospitals whose entire revenue is applied to the support of the institutions. S 746 proposes to require all pupils attending a public high school or a private school, all pupils attending a public or private elementary grade or high school, every student attending a state teacher's college and every faculty member and employee of every school district and state teachers' college to be given a standard chest **x-ray examination** for the presence or absence of tuberculosis at certain stated intervals.

South Carolina

Bill Enacted.—S. 236, which has become governor's act 547 of the Acts of 1947, proposes the *establishment of a* **state cancer clinic.**

Wisconsin

Bills Enacted.—A. 237, which was *approved* May 23, 1947, amends the law relating to chiropractic by **defining a chiropractor** as a person holding a license issued by the state board of examiners in chiropractic. S. 162, which has become chapter 132 of the Laws of 1947, requires all physicians to report immediately to the local health officer the name, age and address of every person diagnosed as afflicted with **epilepsy or similar disorders** characterized by lapses of consciousness.

GOVERNMENT SERVICES

ARMY

STRAIN ON PILOTS AND AIRCRAFT

The experience of army pilots flying the newest jet fighter planes indicates that, regardless of how well the aircraft are built, the human body is capable of greater strain for very brief periods than the aircraft. Such fighter craft are now being equipped with accelerometers to warn the pilots when a critical strain is being approached. The jet fighters are built to withstand successfully a force twelve times the force of gravity. This is much more than an airplane develops generally while performing acrobatics and much greater than a pilot would be able to stand for more than a few seconds. The accelerometers, however, have shown that in some instances pilots have pulled up to 14 g during acrobatics in rough air; the high speed jet aircraft can develop up to 7 g in turbulence. While these forces are dangerously high, the pilot is exposed to the high gravity force for less than one second and has experienced no ill effects. In the case of the jet fighter however, the exposure to any force greater than 12 g for even a part of a second damages the wings and fuselage. The accelerometer will enable the pilots to reduce the chances of such damage. A force of 1 g is equal to the pull of gravity. A force recorded as 4 g would be four times the force of gravity, and a pilot weighing 200 pounds would weigh 800 pounds when exposed to 4 g.

FLIGHT NURSES

Nine flight nurses, officers of the Army Nurse Corps, graduated from the School of Aviation Medicine, Randolph Field, Texas, May 16, after a five weeks course devoted to basic military medical and surgical subjects and to special consideration of the nursing of wounded during flight. During the last four weeks of the course actual air evacuation flights are used in on-the-job training.

TRANSLATION SERVICES DISCONTINUED

The Army Medical Library, Washington, D. C., as of May 1 discontinued all public translation functions of the library. While during the war the translating section rendered valuable services, demands for translations have lessened and the section can no longer be maintained as a separate unit. The personnel of the section will be detailed to the Index-Catalogue Division.

LIBRARY EVENING HOURS

Because of an increasing demand for evening hours the Army Medical Library, Washington, D. C., will remain open until 9 o'clock on Wednesday evenings but will no longer be open on Sunday mornings. The library closes at 5 p. m. on other days and is open Sundays from 1 to 5 p. m.

PROFESSIONAL STAFF PROGRAMS

The Army and Navy General Hospital, Hot Springs National Park, Ark., and Walter Reed General Hospital, Army Medical Center, Washington, D. C., have forwarded staff programs which outline for each day the professional activities at those institutions. These comprise in one or the other hospital clinical conferences, ward rounds, formal teaching ward rounds, seminars, case presentations and medical motion pictures.

NAVY

COMMENDS NAVAL DISASTER ACTIVITIES

The Surgeon General, Rear Admiral Clifford A. Swanson, has highly commended the naval activities in Texas for their contribution to Texas City and to the hospitals at Galveston at the time of the disaster. The medical personnel from the Naval Hospital at Houston, who were the first military organization to arrive at the scene of the explosion, some 46 miles distant, worked with the civilian doctors and first aid teams in the vicinity of the docks until the injured were evacuated and until the area became too dangerous for further work. The commanding officer of this hospital then made available 500 beds for the injured.

The medical group from Orange, Texas, flew directly to Galveston and reported to the John Sealy Hospital, formed a surgical team, were assigned a surgery, and worked through the night taking care of the injured. A second team from Orange formed a caravan and drove the 110 miles to Houston and worked at the Houston Naval Hospital, substituting there for the naval personnel who went to Texas City. The medical personnel from Dallas and Corpus Christi, who arrived by plane in the early afternoon, set up a first aid station at the Naval Air Field, Hitchcock, about 15 miles distant, and for forty-eight hours cared for more than 300 refugees and seriously injured.

On the afternoon of the explosion the medical officer in command of the Naval Hospital, Houston, Capt. Clyde W. Brunson, U.S.N., and Rear Admiral A. S. Merrill, commandant of the 8th Naval District, made a visit to Texas City and to all hospitals in Galveston and offered all available medical facilities. Later the Naval Hospital, Houston, became the headquarters for dispensing supplies in that area to both Texas City and Galveston, and the needed supplies were sent practically every hour, day and night. Casualties were also received at this station.

For this exceptionally meritorious work and for the long hours spent without rest in aiding the injured, the Surgeon General stated that he was exceptionally appreciative of the manner in which the personnel from these naval activities conducted themselves in this emergency and that their actions were in accordance with the highest tradition of the medical department of the naval service.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Ralph D. Eichhorn

The Navy Commendation Ribbon has been awarded to Lieut. Ralph D. Eichhorn (MC), U.S.N.R., of New York, for excellent service in the line of his profession and duty as junior medical officer aboard the U. S. S. *Ormsby* (APA-49) from Feb. 1 to Nov. 15, 1944 during the amphibious assaults and capture of Kwajalein, Aitape, Guam, Pelelieu and Leyte. The citation states that Lieutenant Eichhorn's exceptional leadership was a source of inspiration to medical department personnel. He demonstrated sound judgment, resourcefulness and high professional skill in meeting unique problems in surgery. During the assault on Guam he attended to the wounded continuously for seventy-two hours without rest and sleep and thus saved many lives. His conduct and accomplishments under hazardous combat conditions were in keeping with the highest traditions of the naval service. Dr. Eichhorn graduated from New York University College of Medicine in 1942 and entered the service Dec. 14, 1942.

PERSONAL

Captain O. L. Burton, chief, preventive medicine division, Bureau of Medicine and Surgery, returned from the fifth annual meeting of the United States-Mexico Border Public Health Association, held at Tijuana, Mexico, where he read a paper on venereal disease problems. This group reduced the venereal disease rate at the Mexican border areas and during the war solved public health problems by joint actions which were of concern to the two countries.

VETERANS ADMINISTRATION

CENTRAL LABORATORY ESTABLISHED

The Veterans Administration announces the establishment of a central laboratory for pathology in Washington, D. C., in cooperation with the Army Institute of Pathology, to provide a consultation, review and diagnostic service in pathologic tissues for the 126 hospitals and other medical facilities of the Veterans Administration. In addition, Veterans Administration pathologists will cooperate with the Army, civilian medical societies and others in maintaining a central file of pathologic anatomy and related records for reference, research, training and long-range follow-up programs. The joint laboratory will also provide instruction in pathologic anatomy and histopathologic technics for Veterans Administration pathologists and technicians within the limits of available facilities, conduct research in the pathology of diseases, cooperate with similar research programs of the Army Institute of Pathology and provide study and review material in the form of study sets, atlases and clinicopathologic conferences. It is planned that branch reference laboratories, to be established in thirteen branch offices of the Veterans Administration, will later maintain consultation and training services in pathology for Veterans Administration hospitals and other medical facilities within their respective areas.

NEUROSURGERY CENTERS

Veterans in need of surgery of the nervous system now are sent to forty-one specially equipped and staffed hospital centers operated by the Veterans Administration or under contract. Thirty-seven of these centers are in Veterans Administration hospitals. Eligible veterans may also be treated in navy hospitals at Philadelphia, at Houston, Texas, in the Army's Fitzsimons General Hospital, Denver, or in the Maine General Hospital, Portland. Each of the forty-one centers has special equipment, neurosurgeons and other skilled personnel necessary to perform all types of neurosurgical operations.

NEW CONCEPT OF NURSING PRACTICES

The Veterans Administration nursing service is pioneering in a new concept of nursing practices to give American veterans the best possible care. The announcement was made by Miss Dorothy V. Wheeler, director of the Veterans Administration's nursing service, after the major changes had been approved by Dr. Paul R. Hawley, chief medical director. The four major shifts in policy include (1) creation of professional standards boards to evaluate qualifications for appointment to the nursing service, just as physician boards now evaluate the qualifications for doctors; (2) new regulations revising the promotion of nurses so that the more proficient may be promoted to positions in line with their abilities; (3) establishment of a rotation policy transferring nurses in isolated Veterans Administration hospitals to hospitals with teaching units so they may keep abreast of the latest professional technic; (4) complete revision of nursing policies to increase the degree of nursing care given each veteran patient.

EXERCISE FOR PARALYZED VETERANS

Veterans paralyzed from the waist down now can play table tennis with ease from wheel chairs in Veterans Administration hospitals as a result of a specially built table designed for their use. The table is standard except for sideboards 30 inches high that extend above the playing surface and prevent the ball from glancing off the table. Two changes in the rules have been made to fit the needs of these players. The first provides that a serve may not strike the sideboard before it crosses the net; the other change involves a ball hitting the sideboard and then going off the table before it bounces on the table. This shot is scored against the player making it. These tables and other arrangements for athletic activities for paralyzed veterans not only entertain patients but provide an adjunct to their treatment in veterans' hospitals.

PROPOSED HOSPITAL AT HOUSTON, TEXAS

Construction is expected to get under way soon on the veterans' hospital to be located on a 209 acre tract a short distance from the Texas Medical Center and the new navy hospital in Houston, Texas. The twenty-five hospital buildings, costing around fifteen million dollars, will provide care for veterans in all branches of medicine, convalescence and rehabilitation. The hospital will be equipped for medical research also. Great emphasis will be placed in the planning on mental and spiritual restoration for veterans and for vocational instruction. In addition to a wide variety of facilities for athletics, physical development, training in manual art and many branches of education there will be an experimental farm for teaching rehabilitated veterans modern methods of agriculture.

PERSONAL

Dr. Edwin J. Euphrat, chief, radiologic service, U. S. Veterans' Hospital, Aspinwall, Pa., has returned to Elkins, W. Va., and accepted appointment as chief, department of radiology, Davis Memorial Hospital, Elkins.

Dr. Seldon R. Hoover, Charlestown, W. Va., has accepted appointment as urologist at the Veterans Administration office in Huntington, W. Va.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration is conducting sales of surplus government property announced by the following regional offices. Physicians who are veterans have certain priorities in the purchase of this government property.

Regional Office, 600 Washington Street, Boston 11. Sale of miscellaneous medical equipment. Sale closes June 12.

Regional Office, 95th and Troost, Kansas City, Mo. Sale of laboratory supplies and equipment, hospital equipment and supplies, one lot of surgical instruments and supplies, one lot of surgical chemicals, one lot of orthopedic accessories, one lot of restraint apparatus, one lot of splints and splint accessories. Sale closes June 18.

Regional Office, 412 West Market Street, Louisville, Ky. Sale of surgical supplies and of a large quantity of synthetic rubber gloves at 9 cents a pair. Sale opens June 6 and will be continuous.

SALE OF ANESTHETIC AGENTS

The War Assets Administration is offering $220,000 worth of government surplus anesthetic agents in a fixed price sale. The offering will be concurrent to priority claimants and other buyers until June 12, with orders being filled in the usual priority sequence. The offering includes evipal soluble powder in 1 gram ampules ranging in price per package of ten ampules from $3 to wholesalers and exporters to $3.60 to small retailers; avertin solution in 100 cc. bottles priced at from $6 to $7.20 to the various levels of trade; spinocaine solution in boxes of ten 2 cc. ampules priced at from $1 to $1.25 each, and procaine hydrochloride in boxes of ten ampules of 100, 120 and 150 mg. each at prices ranging from 30 cents to 36 cents a box. All prices are f. o. b. location. The surplus avertin solution is located in both the St. Louis and Louisville W. A. A. regions and the other items are located only in the Louisville region. Orders should be sent in duplicate to the W. A. A. region having the desired products. Brochures containing complete price listings and other details of the offering will be available at W. A. A. regional offices and customer service centers.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

Dr. Noland Honored.—At a reunion of the medical staff of the Employees Hospital (Fairfield) of the Tennessee Coal, Iron & Railroad Company in Birmingham, May 16, more than half of the 248 interns who have worked with Dr. Lloyd Noland, Birmingham, at the hospital returned to pay him honor on completion of thirty-four years' service with the company. Part of the ceremony was in the nature of a surprise party in that Dr. Noland's six brothers and sisters, who had not been together for many years, were present. A book was presented to him, also as a surprise, containing a list of the interns and staff members with whom he had served throughout the years, and a number of medical papers published for the first time by eminent authorities. The book, which also contained a biography, had been prepared by a committee headed by Drs. E. Bryce Robinson Jr., Hillary H. Henderson Jr., Wallace A. Clyde and Russell G. Hightower, all of Fairfield. Dr. Noland came to Birmingham from the Panama Canal Zone, where he had been an assistant to General William C. Gorgas. He founded the three and half million dollar Tennessee Coal and Iron hospital. His experience in the tropics has enabled him to reduce greatly the number of cases of malaria among the company's employees.

CALIFORNIA

Physicians' Hobby Show Revived.—The Alameda County Medical Association plans to revive its hobby show, discontinued during the war, next fall. The society claims it was one of the first counties in the West to sponsor a show displaying hobbies of physicians. Doctors' Hobbies, Inc., was formed in 1940.

Narcotic Violation.—Dr. Paul O. Meyer, 327 Beloit Avenue West Los Angeles, was charged with prescribing narcotics to an addict or person representing himself as such and on February 17 was sentenced to serve six months in the county jail of Los Angeles County on a guilty plea to misdemeanor charges of issuing false prescriptions. The jail sentence was suspended and the doctor was granted probation for two years provided he pay a fine of $500 to the probation department.

Poisonous Mussels.—The annual quarantine order of the state department of health forbidding the gathering of mussels from ocean and bay waters in California became effective May 1 and will extend to October 31. The quarantine extends from Oregon to the Mexican boundary. During the summer months, cases of death among those who violate the order are usually reported to the state department of public health each year. In 1946, 3 cases and 1 death were reported from San Mateo County. Since 1927 there have been 345 cases and 24 deaths reported.

CONNECTICUT

Central Medical Association Centennial.—The Central Medical Association observed its centennial, April 9, at a meeting in Essex. The guest speaker was Dr. Morris Fishbein, Chicago, editor of The Journal, who discussed "The Motivation of the American Medical Association." Dr. James Murphy, Middletown, was presented a gold pen and pencil set in honor of his fifty-two years in the practice of medicine. Dr. Murphy related incidents in the practices of some of the early members. An interesting feature was an exhibit of excerpts from the old records of the association. The Middlesex County Medical Association held its annual meeting in conjunction with the Central Medical Association.

Dr. Bayne-Jones to Head Medical Center.—Dr. Stanhope Bayne-Jones, professor of bacteriology, Yale University School of Medicine, New Haven, and director of the board of scientific advisers, Jane Coffin Childs Memorial Fund for Medical Research, has been appointed president of the Joint Administrative Board of the New York Hospital-Cornell Medical Center. Dr. Bayne-Jones was dean of the Yale School of Medicine from 1935 to 1940. A veteran of both world wars, he was deputy chief, preventive medicine service, in the Office of the Surgeon General and director of the United States Typhus Commission from 1942 to 1946. Separated with the rank of brigadier general, he is still medical consultant to the Army Epidemiologic Board, Army Research and Development Board. Dr. Bayne-Jones was awarded the Charles V. Chapin Medal by the city of Providence, R. I., in recognition of his achievements in the control of typhus. The presentation took place at the 136th annual meeting of the Rhode Island Medical Society, May 14-15.

FLORIDA

State Medical Election.—At the meeting of the Florida Medical Association, April 21-23, Drs. William C. Thomas, Gainesville, was installed as president; Joseph S. Stewart, Miami, was named president-elect; Frank W. Hewlett, Miami, Frank D. Gray, Orlando, and Bricey M. Rhodes, Tallahassee, first, second and third vice presidents respectively, and Robert B. McIver, Jacksonville, secretary-treasurer. Nearly 1,000 members attended the three day convention.

ILLINOIS

State Medical Election.—At the annual meeting of the Illinois State Medical Society, Chicago, May 12-14, Dr. Irving H. Neece, Decatur, was installed as president and Dr. Percy I. Hopkins, Chicago, was chosen president-elect. Drs. H. Kenneth Scatliff, Chicago, and Walter E. Kittler, Rochelle, were chosen first and second vice presidents respectively. The council of the society authorized holding twelve postgraduate conferences in its eleven councilor districts 1947-1948. The next annual meeting was tentatively set for May 10-12 at the Palmer House, Chicago.

Chicago

University of Illinois Banquet.—An informal Alumni-Faculty-Student banquet will be held by the University of Illinois College of Medicine June 19 at the Furniture Club, 666 North Lake Shore Drive, at 6 p. m. Nonfaculty alumni should make reservations with Dr. Michael H. Streicher, secretary, 1853 West Polk Street. Guests are invited. Cost per plate is $5. Class reunions will be held for the years 1897, 1902, 1907, 1912, 1917, 1922, 1927 and 1937.

Committee to Publish Chicago-Cook County Health Survey.—In view of the public interest in the Chicago-Cook County Health Survey and the many requests for copies of the report, the advisory committee has decided to publish a nontechnical summary of the report. The booklet, about 40,000 words in length, will include a summary of the recommendations for the survey as a whole and a summary of the findings for each of the forty sections of the report.

Personal.—The Illinois Public Health Association April 19 elected Dr. Edward A. Piszczek, Chicago-Cook County health officer, as president.——Dr. Frode Jensen, member of the staff of the Council on Medical Education and Hospitals of the American Medical Association, has resigned to accept a position as director and coordinator of graduate and postgraduate medical education, University of Colorado School of Medicine, Denver, where he will also be an assistant professor of medicine in the department of internal medicine. He will be succeeded by Dr. William R. Albus, formerly of Washington, D. C., and recently of Chicago.

KANSAS

Logan Clendening Memorial.—A fountain in a court yard of the University of Kansas Hospitals, Kansas City, was dedicated to the memory of Dr. Logan Clendening at services April 20. Dr. Clendening, who died Jan. 31, 1945, was a widely known member of the faculty of the University of Kansas School of Medicine, Kansas City. He came to the university in 1910 as an instructor in the department of internal medicine and had served as professor of the history of medicine for many years.

KENTUCKY

Rehabilitation Center to Open in Louisville.—The Kentucky Society for Crippled Children will open a curative workshop for children and adults in Louisville within the next few months. This rehabilitation center is designed to assist the orthopedic handicapped patient to obtain maximum use of the injured part and to help him resume his normal place in the community. The types of treatment will be physical and occupational therapy. All treatment will be given only on medical recommendation. A committee has been appointed by the Jefferson County Medical Society to advise and cooperate with the local workshop committee. The types of cases will include persons suffering from fractures, cut tendons and amputations and persons suffering from infantile paralysis and cerebral palsy, as well as other handicapping disabilities. At present there is no such restoration center in Kentucky.

LOUISIANA

Eye Bank in New Orleans.—An eye bank which will serve as a branch of the Eye Bank for Sight Restoration, Inc., in New York is to be established in New Orleans, Mrs. Henry Breckinridge, director of the New York eye bank, has announced. The bank will be housed in the new wing of the Eye, Ear, Nose and Throat Hospital, but until it is constructed the bank will be located in the Tulane Medical School building.

Louisiana-Mississippi Ophthalmological and Otolaryngological Society.—This society held its annual meeting at Biloxi, Miss., on May 5. Among the speakers were Dr. Samuel Fomon, New York, "The Rhinoplastic Operation and the Restoration of Nasal Function"; Dr. Peter C. Kronfeld, Chicago, "Newer Trends in the Treatment of Ocular Diseases"; Dr. Henry L. Williams, Rochester, Minn, "Ménière's Disease," and Dr. Ralph Bowen, Houston, Texas, "Allergic Problems Seen by the Ophthalmologist and Otolaryngologist." Dr. Noel Simmons, Alexandria, La., was elected president, and Dr. Edley H. Jones, Vicksburg, Miss., was relected secretary. The 1948 convention will be held in New Orleans.

MAINE

State Medical Meeting.—The ninety-third annual session of the Maine Medical Association will be held at the Marshall House, York Harbor, June 22-24 under the presidency of Dr. John O. Piper, Waterville. Conferences have been planned for Monday and Tuesday on spinal anesthesia, deafness, metabolic diseases, sterility, allergy, the eye, urology, pediatrics and orthopedics. A symposium on gallbladder disease is scheduled for Tuesday morning. Among the speakers at the scientific sessions are:

Dr. Garfield G. Duncan, Philadelphia, Treatment of Acute Complications of Diabetes.
Dr. Richard B. Cattell, Boston, Management of Obstructive Jaundice.
George L. Maltby, Portland, The Problem of the Ruptured Intervertebral Disk.
Dr. Edwin B. Astwood, Boston, Propylthiouracil.
Dr. Richard H. Sweet, Boston, Diagnosis and Treatment of Mediastinal Tumors.

At the dinner Monday evening at 7 o'clock Dr. Winthrop Adams, Bedford, Mass., will speak on "Medical and Hospital Care of Veterans under Veterans Administration." Other speakers include Dr. Abraham Colmes, Boston, "Food Allergy," and Dr. Edward S. O'Keefe, Lynn, Mass., "Pediatric Allergy." The annual meeting of the Maine Medico-Legal Society will be held Tuesday morning at 9:30. Drs. LeMoyne Snyder, Lansing, Mich., and A. Warren Stearns, Billerica, Mass., will be the speakers.

MASSACHUSETTS

The Boston Eye Bank.—An affiliated "eye bank" has been organized in Boston and is ready to serve the needs of New England, it was announced at the national headquarters of the Eye Bank for Sight Restoration, Inc., New York, which is celebrating its second anniversary. The organization marked its first anniversary last year by announcing an affiliated eye bank in Chicago at Mercy Hospital. The Boston Eye Bank is located in the Massachusetts Eye & Ear Infirmary building at 243 Charles Street. Seven hospitals in the Boston area and one in Maine have already become affiliated with it. The public in New England is being urged to sign forms, available from the Boston Eye Bank, indicating their willingness to donate their eyes for use after death. Henry Hixon Meyer, William S. Ballard and Dr. Edwin B. Dunphy, Boston, constitute the executive committee of the Boston Eye Bank's Board of Sponsors. The board includes leading ophthalmologists throughout New England, business, industrial and religious leaders and representatives of the eye departments of various hospitals.

MICHIGAN

Health Examination for Bartenders.—The Michigan Liquor Control Commission has adopted a law which requires that bartenders, who must renew their licenses each year, must obtain a certificate of health signed by a physician and an officer of the board of health. The certificate must show that the applicant is not affected with any infectious or communicable disease.

Evaluation of Local Health Departments.—The fifty-eight local health departments of Michigan are now completing evaluation of their services on the basis of standards set up by the American Public Health Association. After reports have been submitted to the Michigan Department of Health, where they are graded by the field staff of the Michigan Public Health Association, and follow-up visits by the state department have been made, plans for immediate and long range programs with local health departments will be instituted.

Dr. Baker Wins Russel Award.—Burton L. Baker, Ph.D., assistant professor of anatomy at the University of Michigan Medical School, Ann Arbor, received the annual Henry Russel Award at a ceremony May 8 in Ann Arbor. Mr. Baker, the twenty-second recipient of the Henry Russel Award for achievements in scholarly activity and a promising future, was selected for his research work dealing with the microscopic structure and internal chemistry of cells, especially in relation to their secretory activity. His investigations have centered about the endocrine glands that regulate the physiology of reproduction. Mr. Baker received his Master of Science degree in 1935 from Kansas State College and a Doctor of Philosophy degree in anatomy in 1941 from Columbia University College of Physicians and Surgeons, which he served from 1936 to 1938 as an instructor in anatomy.

Marquette Honors Admiral Swanson.—The Surgeon General of the Navy, Rear Admiral Clifford A. Swanson, was guest of honor at a three day "homecoming" at Marquette recently. Admiral Swanson was born and educated in Michigan. The city's chamber of commerce climaxed the celebration with a dinner attended by about 400 of the city's notables and their guests. Admiral Swanson addressed the dinner group on "Medicine in Action," pointing out the importance of medical service to the naval and military forces in winning a war and maintaining peace. Admiral Swanson was accompanied by Mrs. Swanson and his aide, Lieutenant Commander Arthur H. Nelson, U. S. Navy. Following the dinner he presented to the city a Bureau of Medicine and Surgery plaque which was inscribed "A certificate of appreciation to the city of Marquette, Michigan, in grateful acknowledgment for services rendered to the Medical Department of the Navy in World War II."

NEW YORK

Appointed Director of Association.—Dr. Herbert R. Edwards, New York, director of the Bureau of Tuberculosis, New York City Department of Health, has been appointed executive director of the New York Tuberculosis and Health Association to succeed Dr. Frank Kiernan on his retirement September 1.

New York City

Gift of $250,000 to Cancer Fund.—A check for $250,000 from the Damon Runyon Memorial Fund was presented to the American Cancer Society recently as "a first instalment only" toward cancer research. Brig. Gen. John R. Kilpatrick, chairman of the New York Cancer Committee's 1947 drive, said that part of the sum would be used to establish a pavilion in memory of Mr. Runyon in Memorial Hospital for the Treatment of Cancer and Allied Diseases. A large part of the gift will go for the care of newspapermen stricken with cancer.

Physicians Honor Sisters for Cancer Work.—At the fifteenth anniversary of the founding of their first cancer clinic Dr. Elise Strang L'Esperance and her sister Miss Mary Strang were honored for their work in cancer prevention at the New York Infirmary May 18. More than one hundred and fifty physicians attended. A scroll was presented to them by Dr. Ruth M. Bakwin, chairman of the medical board of the infirmary. Dr. George Baehr, president, New York Academy of Medicine, described how the impact of their interest in cancer prevention had spread widely. The sisters' first clinic at the infirmary, which was started in honor of their mother, became known as the Kate Depew Strang Cancer Clinic.

Library Donated for Jewish Doctors in Europe.—The New York Academy of Medicine has donated twelve thousand textbooks and medical journals to the book campaign of the Supplies for Overseas Survivors collection of the Joint Distribution Committee. This library will be sent to Jewish doctors and other professionals in Europe whose personal libraries were looted and destroyed by the Nazis. Selection of this material from the storehouse of the Academy of Medicine was supervised by Dr. Archibald Mallock, librarian of the New York Academy of Medicine, and Miss Libby Vernon, head of the storehouse division. The books and journals, printed chiefly in English, French, German, Russian and Yiddish, contain information pertinent to the treatment of tuberculosis, anemia and other diseases prevalent in postwar Europe. In addition to medical books and journals the Supplies for Overseas Survivors book campaign seeks fiction, poetry and other cultural reading material. Picture books for children have also been requested overseas. The Supplies for Overseas Survivors collection is a project of the Joint Distribution Committee in cooperation with sixteen national Jewish women's organizations and other groups.

OHIO

Smallpox in Fostoria.—Vaccinations were ordered by health officials of Fostoria following the death of a 73 year old Mexican who came to Fostoria early in May from Savina, Mexico, with a truckload of other Mexican workers who are scattered over northwest Ohio. Vaccine was rushed to the city from Toledo, Columbus, Detroit and New York.

Research on Toxins and Toxoids.—Western Reserve University School of Medicine, Cleveland, has received $31,000 from the Lederle Laboratories to support research on bacterial toxins and toxoids, bringing the total given by Lederle to $46,000 in the last two years. Work under the direction of Louis Pillemer, Ph.D., associate professor of immunochemistry, has produced two purified toxoids, those of tetanus and diphtheria. The toxoids produced by Dr. Pillemer and his staff, it is claimed, have been found to be many times purer than the toxoids formerly used.

OKLAHOMA

Physicians Aid Tornado Stricken Woodward.—When news of the tornado that devastated the city of Woodward April 9 reached the executive secretary of the State Medical Association at 12:15 a. m., he immediately contacted doctors and nurses from nearby communities, who made up the first rescue party. Eleven private and four army physicians and nine nurses and technicians who assembled at the Highway Patrol headquarters were flown to Woodward through the cooperation of the Army Air Forces at Tinker Field. The plane, also carrying medical supplies secured from the state health department, the Red Cross and the Station Hospital at Tinker Field, departed at 2:45 a. m. and was met at Gage air field by citizens from both Shattuck and Woodward. The doctors, nurses and technicians and medical supplies were divided between these two towns. The personnel remained on duty until late the following day, when additional medical assistance arrived. Meanwhile senior medical students, interns and residents from Oklahoma City rendered valuable assistance. The next morning doctors came from as far away as Wichita, Kan., and Amarillo, Texas, and from many cities of the surrounding areas. The seriously wounded were evacuated by air to Oklahoma City hospitals. Patients were evacuated to the hospital at Alva by train, and the more seriously injured were transported to Community Hospital at Mooreland and a temporary hospital set up at the Baker Hotel, Woodward. No fuel or water until the following morning made emergency care and operative procedures at Woodward almost impossible. The public health department moved in at once to supervise and protect the people from epidemics occasioned by breaking of water and sewage mains. As late as the third day it was still necessary to take medical care into the area, for some of the injured were in too serious a condition to be evacuated. Of the 74 persons, including children, evacuated to University Hospital, Oklahoma City, only four fatalities resulted. At the hospitals long-stay cases were diffused so those less injured could be cared for as quickly as possible and normal services of the hospitals could be resumed. Hundreds of persons in Woodward had injuries that were not emergencies but which required care, and, as late as twenty-four hours after the tornado, people reported for aid with minor fractures, exhaustion and hysteria. Pebbles and splinters were driven into their skin and bodies. The catastrophe showed the definite need for establishing statewide disaster planning, as there was little coordination of available facilities. Medical supplies were scarce. Although long lines of people waited to give blood, there was insufficient equipment to give transfusions.

PENNSYLVANIA

Centenaries in Pennsylvania.—Two medical organizations are celebrating or approaching celebration of their one hundredth anniversaries this year. The Montgomery County Medical Society has been in existence one hundred years, and on May 10 Mercy Hospital of Pittsburgh completed one hundred years of service as a general hospital to the people of the tri-state area. In 1948 the Lycoming County Medical Society and the Medical Society of the State of Pennsylvania will observe their centennials.

State Society Plans Graduate Courses.—Plans for a statewide graduate course in medicine to be taken to the general practitioners in rural areas by traveling teams of lecturers have been endorsed by the board of trustees of the Medical Society of the State of Pennsylvania. Six teaching centers have been selected where seminars on the fundamentals of medicine will be given one day a week for ten weeks beginning in the fall: Allentown, Harrisburg, Johnstown, Oil City, Wilkes-Barre and Williamsport. Headed by Dr. Charles W. Smith, Harrisburg, the committee on graduate education includes the deans of the six medical colleges of Pennsylvania and officers of the state society. An advisory committee of medical leaders from Pittsburgh, Philadelphia and Harrisburg met in Philadelphia and formulated plans May 15. The lecturing teams will consist of four men. The schedule has been so arranged that lecturers from the five medical colleges in Philadelphia will cover the central and eastern sections of the state and those from the University of Pittsburgh School of Medicine will assume most of the teaching of the western centers. The state society believes its program is the largest statewide postgraduate education program scheduled in this country, although state medical societies in Wisconsin, Michigan, New York and other states have postgraduate training programs.

Philadelphia

Mine Workers Fund for Occupational Diseases.—Jefferson Medical College of Philadelphia has announced establishment there of a fund of $575,000 by the United Mine Workers of America for research and treatment of occupational diseases found among anthracite coal workers. Known as the Anthracite Health and Welfare Fund Foundation, it will finance treatment, care and rehabilitation, and research into the nature and prevention of silicosis and safety measures looking toward prevention of the disease. The gift enables the hospital to expand work that has been under way for years. The fund will contribute to the operation of a program that will include instruction of medical students, interns and resident physicians in the problems of silicosis; cooperation of the alumni of Jefferson Medical College of Philadelphia practicing in the anthracite coal regions; cooperation with physicians in the coal regions and elsewhere to facilitate the study and care of their patients, and the dissemination of scientific reports and medical papers.

WEST VIRGINIA

Lifetime Members of State Association.—The following doctors have been elected by the council as honorary lifetime members of the West Virginia State Medical Association: Edward Davis, Salem (Harrison); William T. McClellan, Ethel (Logan); Thomas C. Smith, Slagle (Logan); George R. Miller, Fairview (Marion); Robert A. Ashworth, Benjamin F. Bone, Orra F. Covert and Joseph A. Striebich, all of Moundsville (Marshall); Richard V. Shanklin, Bluefield (Mercer); Donald M. Post, Lawrence, Ind. (Monongalia); Paul C. Spangler (Morgantown, N. C. (McDowell); Frank D. Fortney, Beckley (Preston); Elmer E. Watson, Kingwood (Preston), and Francis E. Martin, New Martinsville (Wetzel).

County Health Bureau Director.—Dr. Alexander Witcow, city-county health commissioner, Delaware, Ohio, has been appointed by Dr. Newman H. Dyer, Charleston, W. Va., state health commissioner, as director of the bureau of county health work, to succeed Dr. Norman G. Angstadt, who resigned to accept appointment as director of the department of medical supervision of the school district of Reading, Pa. Dr. Witcow is a graduate of the New York University College of Medicine and received his master's degree in public health at Yale University, New Haven. Prior to going to Delaware he served as director of the health department of Menominee County, Mich., and afterward as director of the Dickinson County (Mich.) health department.

WISCONSIN

Wisconsin Surgical Society.—At the semiannual meeting of the Wisconsin Surgical Society, Madison, May 15, Dr. Claude Dixon, Rochester, Minn., addressed the society on "Anterior Resection of Lesions of the Lower Sigmoid and Rectum." The day's program consisted of morning operative clinics at the Wisconsin General and Methodist hospitals, case presentations and papers by members of the Jackson Clinic at the Methodist Hospital in the afternoon and a dinner meeting at which addresses were given by Dr. Russell M. Kurten, Racine, and the guest presentation by Dr. Dixon. Newly elected officers are Drs. Kurten, Racine, president; Erwin R. Schmidt, Madison, president-elect; Warner S. Bump, Rhinelander, secretary-treasurer; Frank D. Weeks, Ashland, recorder. Newly elected members of the council are Drs. Joseph W. Gale, Madison, and Peter A. Midelfart, Eau Claire. A combined meeting with the Chicago Surgical Society is being planned for October in Chicago.

GENERAL

Societies for Experimental Biology.—About one thousand papers were presented before the various meetings May 19-23 in Chicago of the Federation of American Societies for Experimental Biology. The federation is composed of the American Physiological Society, American Society for Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics, the American Society for Experimental Pathology, American Institute of Nutrition and the Association of Immunologists.

Electroencephalographers' Meeting.—The annual meeting of the Eastern Association of Electroencephalographers was held May 24 at the New York Hospital, New York. Following an inspection of laboratories, Wladimir T. Liberson, Hartford, Conn., spoke on "Place of Electroencephalography in the Psychiatric Hospital," and Dr. Margaret A. Kennard, New York City, "The Electroencephalogram in Behavior Problems." During the afternoon Dr. Donald J. Simons, New York, discussed "Electroencephalography in Psychopathic Personalities."

Biological Photographic Exhibition.—An international exhibition of biological photography will be held September 10-27 in Rochester, N. Y., in conjunction with the convention of the Biological Photographic Association. The committee desires to include all photographic technics in the preparation of black and white and color, still and motion picture photographic material. Entry blanks for contributors may be secured from Mr. H. Lou Gibson, 343 State Street, Rochester 4, N. Y. The entry fee is one dollar in United States currency. The last day for receiving entries is August 1, 1947.

Resolution on Delay in Appointments to Hospital Staffs.—The Board of Regents of the American College of Surgeons at a meeting in Hot Springs, W. Va., April 24, carefully considered the problem of helping veterans and other young surgeons in obtaining appointments. The deliberations resulted in the adoption of the following resolution:

> WHEREAS, It has come to the attention of the American College of Surgeons that many well trained surgeons, especially returned veterans, who have located or have signified their intention of locating in communities where there are hospital facilities, have been denied hospital privileges until they have been in residence in that locality for six months to a year; be it
>
> *Resolved*, That the Board of Regents of the American College of Surgeons disapproves of the practice, and, although fully cognizant of the shortage of hospital beds, the Board believes that such well trained, competent and ethical individuals should be given opportunities similar to those offered to established medical practitioners of the community

Cancer Study Grants Total Three Million Dollars.—Nearly $3,000,000 in grants for cancer research was distributed during 1945 and 1946 to finance two hundred and forty research projects in forty-eight universities, hospitals and other institutions, the American Cancer Society has announced Research has turned special interest on the basic element on the growth of cells. As a result of initial work and a recent survey, a special panel of cell chemistry has estimated that $500,000 could be well spent annually in research in this field alone. Another project is investigating a possible effect on malignant growth of the enzyme systems. A vast amount of further study is recommended particularly to explore the effect of hormones and nucleotides on enzyme action. Projects under direction of the panel on virus are tracing the action of viruses in the cell through the use of radioactive substances produced at Oak Ridge, Tenn. The American Cancer Society has appropriated $100,000 for the purchase of stable isotopes.

Outbreak of Hoof and Mouth Disease in Mexico.—In a concerted effort by the Mexican and United States governments to eradicate a serious outbreak in Mexico of hoof and mouth disease, an average of 700 head of cattle, sheep, swine and goats are being killed daily. A board of agricultural experts are directing the battle against the disease, which threatens to spread to the United States. Maurice S. Shahan, D.V.M., co-director of the hoof and mouth commission in Mexico City, said on May 26 that the disease had advanced to within 300 miles of the United States but believed it had been checked. The United States closed its borders to Mexican cattle last December when the disease was officially diagnosed The strategy of the board calls for cleaning up the fringe of the border of the area affected and gradually working toward the center. There have been seven outbreaks in the United States since 1870, the last two in 1924. The cost of eradicating the disease is being split, and $9,000,000 has been appropriated by the United States to share its cost in the early part of the campaign.

Fifth International Congress of Pediatrics Program.—The International Pediatric Congress will meet at the Waldorf-Astoria, New York, July 14-17 under the presidency of Dr. Henry F. Helmholz, Rochester, Minn. Program Chairman Dr. Rustin McIntosh has announced that, because American physicians are hosts, platform privileges have been given to authorities from throughout the rest of the scientific world. The program has been arranged with major sessions on nutrition Tuesday afternoon and on tuberculosis Thursday morning. Minor session subjects Wednesday morning and Thursday afternoon are Diseases Caused by Filtrable Viruses, Chemotherapy of Infectious Diseases, Neonatal Mortality, Incompatibility of Blood, Alimentary Toxicosis and Congenital Heart Disease. Sectional meetings to be held at the New York Academy of Medicine Wednesday afternoon are on Factors in Pregnancy Affecting the Child, Preventive Pediatrics, Bioimmunologic Procedures, Vitamin Requirements and Avitaminoses, Insect and Other Vectors of Disease, Rheumatic Fever, Endocrinology in Childhood and Miscellaneous Topics.

Mission to Tour Austria and Hungary.—The Interim Commission of the United Nations Health Organization will send a ten member team of health experts on a two month tour of Austria and Hungary this summer to explain the latest advances in scientific medicine to Austrian and Hungarian doctors. The group, organized by the Unitarian Committee of Boston, will be headed by Dr. Maurice B. Visscher, professor in physiology and head of the department, University of Minnesota, Minneapolis. Other American doctors include McKeen Cattell, head of the pharmacology department of Cornell University College of Medicine, New York; John J. Bittner, Ph.D., director of cancer research, University of Minnesota Medical School, Minneapolis; Chester M. Jones, clinical professor of medicine, Harvard Medical School, Boston; Alexander Brunschwig, now of the University of Chicago School of Medicine and, beginning July 1, clinical professor of surgery, Cornell University College of Medicine, New York; Joseph P. Evans, associate professor of surgery, University of Cincinnati, Cincinnati; Stuart C. Cullen, assistant professor of surgery, State University of Iowa College of Medicine, Iowa City, and S. Bernard Wortis, professor of psychiatry, New York University College of Medicine, New York. These men will leave June 26 and will join two Swiss members of the team in Vienna.

The Government's Savings Bond Campaign.—To obtain wider distribution of the securities issued on the public debt so that more Americans can own these bonds and share in the interest rates is the object of the U. S. Treasury Department June-July Savings Bond Campaign. Under the plan, checking account depositors can authorize their banks to deduct from balances each month the purchase price of one or more savings bonds, which will be delivered to depositors and the transaction recorded in periodic bank statements. Series E bonds pay $4 for $3 if the securities are held to maturity in ten years. Treasury Department officials believe the Bond-a-Month Plan is ideal for busy doctors for, once the doctor authorizes this systematic purchase of guaranteed securities, there is no need for any further action on his part. According to Commerce Department studies, the average practitioner's income begins to fall off at age 52½. A number of plans for systematic investment to provide for retirement incomes have been evolved by actuaries assuming the continuation of the sale of Savings Bonds. Following are two samples:

> *Plan A.*—At age *27*, buy a $50 series E bond monthly for $37.50 for ten years. At age 37, as the bonds mature each month, reinvest proceeds, interest and principal ($50) and make an additional investment of $100 a month, purchasing a $200 bond for $150. If all bonds are held to maturity the investor will begin to receive, at age 47, $200 a month, or a return of $24,000 on an original investment of $16,500.
>
> *Plan B.*—At age 30, buy a $100 series E bond for $75 each month for ten years. At age 40, as the bonds mature, reinvest proceeds and add $200 a month, purchasing two $200 bonds monthly. If all bonds are held to maturity, income at age 50 will be $400 a month for ten years, or a return of $48,000 on an original investment of $33,000.

CORRECTION

Review of Motion Picture.—In a review of a motion picture entitled Plaster Casts in THE JOURNAL, May 10, page 208, it was stated that this film was produced during World War I. The statement should have read that it was produced during World War II.

Marriages

CHARLES RAYMOND KIEFER JR., Easton, Pa., to Miss Elizabeth Margaret Herron of Collingswood, N. J., February 18.

JOHN LEE FARRINGER JR., Knoxville, Tenn., to Miss Mary Margaret Smith of Fort Madison, Iowa, March 8.

WILLIAM BURFORD HAHN, Austin, Texas, to Miss Martha Harriett Ethridge of Meridian, Miss., March 7.

Deaths

Percy Starr Pelouze ⊕ Philadelphia; born in Camden, N. J., in 1876; Jefferson Medical College of Philadelphia, 1902; assistant professor of urology at the University of Pennsylvania School of Medicine; specialist certified by the American Board of Urology; member of the American Urological Association; second president and at the time of his death honorary president of the American Neissarian Medical Society; served as consultant to the U. S. Public Health Service; member of the board of directors of the American Social Hygiene Association; in 1926 with Dr. Frederick S. Schofield received the Alvarenga Prize of the Philadelphia College of Physicians; served as cystoscopist at Jefferson Medical College, chief of urologic services, Episcopal Hospital in Philadelphia, and consultant to the Delaware County Hospital in Drexel Hill, Pa.; on the advisory editorial board of the *American Journal of Syphilis, Gonorrhea, and Venereal Diseases*; associate editor of the Cyclopedia of Medicine, Surgery and Specialties; died March 12, aged 70.

Curle Latimer Callander ⊕ San Francisco; Johns Hopkins University School of Medicine, Baltimore, 1917; associate clinical professor of surgery and topographical anatomy at the University of California Medical School; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; associate visiting surgeon, University of California Division, San Francisco Hospital; in 1925, at the Atlantic City, N. J., session of the American Medical Association, received a gold medal for exhibit on surface capillaries in health and in disease; author of "Surgical Anatomy"; died March 30, aged 54, of heart disease.

Jesse Sharp Hixson, San Angelo, Texas; Missouri Medical College, St. Louis, 1899; member of the American Medical Association; fellow of the American College of Surgeons; at one time asistant surgeon at the St. Louis University School of medicine; formerly member of the school board; during World Wars I and II medical adviser to Selective Service boards; medical superintendent of the Shannon West Texas Memorial Hospital; served on the staff of St. John's Hospital; active in establishing San Angelo Junior College; died January 22, aged 77, of arteriosclerotic heart disease and congestive failure.

Frank Warner Bishop, New York; Columbia University College of Physicians and Surgeons, New York, 1912; served during World War I; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the New York Academy of Medicine and the American Medical Association; past president of the New York Clinical Society; past president of the medical board and alumni society of St. Luke's Hospital, where he served in various capacities for many years and where he died March 23, aged 59, of cerebral hemorrhage.

Wilford Daniel Albert, Leslie, Mich.; College of Medical Evangelists, Los Angeles, 1937; interned at the Saginaw (Mich.) General Hospital; died in the University Hospital, Ann Arbor, March 10, aged 39, of brain tumor.

Henry Croskey Allen ⊕ Schwenkville, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1899; served overseas during World War I; formerly burgess of Schwenkville and school physician; died March 5, aged 69, of coronary thrombosis.

Orion T. Arnold, Laredo, Texas; Eclectic Medical Institute, Cincinnati, 1898; formerly associated with the U. S. Public Health Service; died March 12, aged 81, of hemiplegia.

John Anthony Balsiger, White Salmon, Wash.; Cooper Medical College, San Francisco, 1904; member of the American Medical Association; served on the staffs of the Sacred Heart Hospital in Spokane and the Hood River Hospital in Hood River, Ore.; died March 7, aged 70, of heart disease.

Conrad Cullis Bell, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1912; died March 6, aged 58, of angina pectoris.

Clement Campbell Blakely ⊕ Barnum, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; served during World War I; on the staff of the Community Hospital in Moose Lake; died March 26, aged 71, of cerebral hemorrhage.

William Wallace Bonner, Rock Mills, Ala.; Southern Medical College, Atlanta, 1892; member of the American Medical Association; died in Roanoke March 4, aged 80, of coronary embolus.

Harry Bishop Boram, South Bend, Ind.; Eclectic Medical Institute, Cincinnati, 1905; died in the Memorial Hospital March 1, aged 77, of arteriosclerosis.

Harrold K. Bryant, Detroit; Detroit College of Medicine, 1900; died in the Receiving Hospital March 1, aged 70, of burns when his home and office quarters were destroyed by fire.

Robert L. Carrick, Lexington, Ky.; Pulte Medical College, Homeopathic, Cincinnati, 1888; served on the staffs of St. Joseph's Hospital and Good Samaritan Hospital, where he died March 7, aged 81, of cerebral hemorrhage.

Andre Aloysius Castaldi, New York; Eclectic Medical College, Cincinnati, 1922; member of the American Medical Association; for many years affiliated with the Bronx Eye and Ear Infirmary; died March 27, aged 53, of coronary thrombosis.

Clarence Henry Christiansen, Superior, Wis.; Marquette University School of Medicine, Milwaukee, 1927; member of the American Medical Association; on the staffs of St. Mary's, St. Francis and St. Joseph's hospitals; died March 8, aged 53, of agranulocytosis and pneumonia.

Harry Sylvester Church, East St. Louis, Ill.; St. Louis University School of Medicine, 1906; died in the Christian Welfare Hospital March 9, aged 66, of heart disease.

Joshua Williams Clarke ⊕ Attleboro, Mass.; University of the South Medical Department, Sewanee, Tenn., 1901; Medico-Chirurgical College of Philadelphia, 1910; veteran of the Spanish-American War and World War I; on the staff of the Sturdy Memorial Hospital; died March 27, aged 76, of coronary disease.

Albert H. Cochran, Atlanta; University of Georgia Medical Department, Augusta, 1897; served as city councilman, alderman and mayor pro tem; died March 5, aged 72, of myelogenous leukemia.

Emmett G. Colvin, Locust Grove, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1899; member of the American Medical Association; died in St. Joseph's Hospital, Atlanta, February 27, aged 69, of carcinoma.

Clarence Weiny Cook ⊕ Los Angeles; University of Southern California School of Medicine, Los Angeles, 1908; on the staff of the Methodist Hospital; died March 2, aged 71, of myocarditis.

George Francis Corrigan, Newark, N. J.; Marion-Sims College of Medicine, St. Louis, 1899; died March 5, aged 68, of coronary disease.

Charles Clement Cropper ⊕ Lynchburg, Ohio; Louisville (Ky.) Medical College, 1897; member of the board of public affairs for many years; died in Alpine, Texas, March 4, aged 75, of diabetes mellitus and heart disease.

Walter Everett Deering ⊕ Los Angeles; University of Southern California School of Medicine, Los Angeles, 1902; affiliated with the Hollywood-Presbyterian Hospital, where he died March 8, aged 69, of cerebral hemorrhage.

Michael Ercole Deluca, ⊕ Troy, N. Y.; Albany (N. Y.) Medical College, 1911; fellow of the American College of Surgeons; on the staff of the Troy Hospital; died March 8, aged 58, of coronary heart disease.

Charles Henry Dixon, St. Louis; Baltimore Medical College, 1894; died in the Barnes Hospital March 9, aged 75, of coronary thrombosis and carcinoma of the colon.

Mary Phylinda Dole, Shelburne, Mass.; Woman's Medical College of Baltimore, 1888; member of the American Medical Association; died February 23, aged 84, of heart disease.

Henry Rhea Douglas, Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; member of the American Medical Association; past president of the Harrisburg Academy of Medicine and the Dauphin County Medical Society; veteran of the Spanish-American War; on the staff of the Harrisburg Hospital; member of the board of directors of the public library; died March 6, aged 71, of arteriosclerosis and chronic nephritis.

Joseph James Dunnigan, Syracuse, N. Y.; New York Homeopathic Medical College and Flower Hospital in New York, 1917; member of the American Medical Association; served during World War I; member and past president of the staff of the General Hospital, where he died March 16, aged 55, of cerebral hemorrhage.

Raymond Edwin Elliott, Rochester, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1915; member of the American Academy of Ophthalmology and Otolaryngology and the American Medical Association; specialist certified by the American Board of Otolaryngology; on the staff of St. Mary's Hospital, where he died March 4, aged 56, of chronic nephritis.

William Thomas Elliott, Berwick, Maine; Dartmouth Medical School, Hanover, N. H., 1900; member of the American Medical Association; affiliated with the Frisbie Memorial Hospital in Rochester, N. H.; died February 26, aged 76, of angina pectoris.

Ernest L. Epperson, St. Louis; College of Physicians and Surgeons, Keokuk, Iowa, 1883; died March 3, aged 87, of myocarditis.

Charlie Welton Evans, Apple Springs, Texas (licensed in Texas by years of practice); member of the American Medical Association; died in Lufkin in March, aged 66, of carcinoma of the liver.

Morris Feintuch, Brooklyn; Long Island College of Medicine, Brooklyn, 1933; interned at the Unity Hospital; served in the medical corps, Army of the United States, during World War II; died July 4, 1946, aged 39, of coronary thrombosis.

William J. Flint, Watertown, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1890; member of the American Medical Association; on the staffs of the House of Good Samaritan and the Mercy Hospital; died March 1, aged 76, of cerebral hemorhage.

Charles Franklin Frosh, Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1909; member of the American Medical Association; on the staffs of the Mount Carmel, White Cross, Mercy and Grant hospitals; died March 1, aged 62, of heart disease.

Ulysses Grant Gallemore, Melber, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1895; died March 2, aged 81, of heart disease and intestinal carcinoma.

James M. Gaume, Salina, Kan.; Ensworth Medical College, St. Joseph, 1906; died February 20, aged 70, of cerebral hemorrhage and hypertension.

William S. Gooch ⊕ Fort Scott, Kan.; Beaumont Hospital Medical College, St. Louis, 1900; for many years county health officer; chief of staff of the Mercy Hospital, where he died February 21, aged 72, of heart disease following an operation on the prostate.

Charles Butler Hamma, Springfield, Ohio; Miami Medical College, Cincinnati, 1892; member of the American Medical Association; formerly assistant director of public health; served during World War I; died February 25, aged 80, of cardiorenal disease and diabetes mellitus.

Clarence E. Hanes, Indianapolis; Eclectic Medical College of Indiana, Indianapolis, 1904; died March 4, aged 73, of cirrhosis of the liver.

John Douglas Harrison, Greenwood, S. C.; Medical College of the State of South Carolina, Charleston, 1911; member of the American Medical Association; served as a member of the National Guard, on the Mexican border and during World War I; on the staff of the Greenwood Hospital; died March 5, aged 59, of coronary occlusion.

Gustave Esaias Henschen, Sherman, Texas; Dearborn Medical College, Chicago, 1904; member of the American Medical Association and honorary member of the State Medical Association of Texas; past president of the Grayson County Medical Society; served in France during World War I; died January 4, aged 72, of myocarditis.

William M. Holman, Lee, Va.; Medical College of Virginia, Richmond, 1890; member of the American Medical Association; died in Richmond February 22, aged 86.

Joseph Will Horton, Monrovia, Ind.; Medical College of Indiana, Indianapolis, 1900; died March 10, aged 77, of coronary occlusion.

James Wilson House, Bruceville, Ind.; Starling-Ohio Medical College, Columbus, 1908; died in St. Vincent's Hospital Indianapolis, March 3, aged 68, of nephritis.

Francis Edward Jones ⊕ White Plains, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1921; served during World War I; on the staffs of the White Plains Hospital and St. Agnes Hospital; found dead March 1, aged 53, of coronary thrombosis.

James M. Judd, Varina, N. C.; Baltimore Medical College, 1897; member of the American Medical Association; past president of the Wake County Medical Society; for many years chairman of the local school board; bank president; affiliated with the Rex Hospital and the Mary Elizabeth Hospital in Raleigh; died March 7, aged 76, of coronary occlusion.

Zygmunt L. Kadlubowski, Detroit; Michigan College of Medicine and Surgery, Detroit, 1899; died in the Wayne County General Hospital March 2, aged 78, of coronary thrombosis and cerebral hemorrhage.

Arthur Dale Kirk ⊕ Flint, Mich.; University of Michigan Medical School, Ann Arbor, 1923; fellow of the American College of Surgeons; member of the Detroit Academy of Obstetrics and Gynecology; served as chairman of the maternal health committee of the Genesee County Medical Society; for many years affiliated with the Hurley Hospital, where he died March 4, aged 46, of uremia.

Bartholomew Kunny ⊕ Baldwin, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; past president of the village of Baldwin; president of the Baldwin Community Hospital; died in South Laguna, Calif., January 28, aged 66, of coronary thrombosis.

Charles Allen Lanon, Pittsburgh; Temple University School of Medicine, Philadelphia, 1916; served as secretary of the National Medical Association; died February 19, aged 56, of cardiorenal disease.

Frieda E. Lippert, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1889; died in the Norristown (Pa.) State Hospital Dec. 3, 1946, aged 80, of arteriosclerosis.

Vernon MacCammon, Arkansas City, Ark.; Kentucky School of Medicine, Louisville, 1898; member of the American Medical Association; local surgeon for the Missouri Pacific Railroad; died January 6, aged 70 of heart disease.

Thomas Henry Magness, Baltimore; Baltimore University School of Medicine, 1901; died February 28, aged 67, of injuries received when struck by a street car.

Damon George Matthews, Milton, Iowa; St. Louis College of Physicians and Surgeons, 1911; member of the American Medical Association; died in Ottumwa January 9, aged 67.

Solomon Mayantz, New York; University of Kharkov Faculty of Medicine, Russia, 1913; died in February, aged 66.

Lawson A. Meeker, Holgate, Ohio; University of Louisville (Ky.) Medical Department, 1897; member of the staff of the Detwiler Memorial Hospital in Wauseon; died February 25, aged 73, of cerebral hemorrhage.

Edward D. Miles, Carthage, Mo.; Missouri Medical College, St. Louis, 1885; died in the McCune-Brooks Hospital March 10, aged 83, of uremia and pneumonia.

Carlton Mitchell, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1898; died in a hospital at Miami Beach, Fla., February 12, aged 85.

Seth Eastman Moore, Palo Alto, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; at one time on the faculty of the University of Minnesota Medical School in Minneapolis; died in the Providence Hospital, Washington, D. C., February 28, aged 71, of cerebral hemorrhage.

Frederick Henry Morhart ⊕ Washington, D. C.; Columbian University Medical Department, Washington, D. C., 1898; served during the Spanish-American War and World War I; director of the Liberty National Bank; died in the Doctors Hospital, March 5, aged 72, of cirrhosis of the liver.

Antonin D. Mueller ⊕ Chicago; Chicago Physio-Medical College, 1896; died March 4, aged 84, of chronic myocarditis.

Ida May Shively Herr Nelson, Sanitarium, Calif.; Northwestern University Woman's Medical School, Chicago, 1897; served on the staff of St. Helena Sanitarium and Hospital, where she died February 11, aged 79, of carcinoma of the intestine.

James Nightingale, Worcester, Mass.; Harvard Medical School, Boston, 1900; member of the American Medical Association; served during World War I; medical director of the Jewish Home for Aged and Orphans; died March 6, aged 70, of cerebral hemorrhage and bronchopneumonia.

Lytle Neale Patrick, Gastonia, N. C.; University of Maryland School of Medicine, Baltimore, 1909; also a pharmacist; for many years city physician; died February 12, aged 63, of cerebral hemorrhage.

George William Payne ⊕ Bardwell, Ky.; Missouri Medical College, St. Louis, 1899; past president of the Carlisle County Medical Society; past president of the school board; active in the chamber of commerce; affiliated with St. Mary's Hospital in Cairo, the Riverside Hospital and the Illinois Central Railroad Hospital in Paducah, where he died March 7, aged 73, of coronary occlusion.

Linton Yancey Pittard, Monticello, Ga.; St. Louis University School of Medicine, 1912; member of the American Medical Association; burned to death February 14, aged 59.

Frank Bert Rasbach, Buffalo; Bellevue Hospital Medical College, New York, 1891; died February 24, aged 80, of transverse myelitis and bronchopneumonia.

George Stiles Reitter ⊕ East Orange, N. J.; Albany Medical College, 1915; specialist certified by the American Board of Radiology; member of the American College of Radiology; served overseas during World War I; consultant to the Essex Mountain Sanatorium in Verona, Essex County Hospital for Contagious Diseases in Belleville and the Essex County Hospital in Cedar Grove; died in the Veterans Administration Hospital in Lyons, March 5, aged 58, of empyema.

Rush Rodger Richison, Springfield, Ohio; Ohio Medical University, Columbus, 1904; member of the American Medical Association; health director of Springfield; formerly county health commissioner; past president, secretary and treasurer of the Clark County Medical Society; at one time mayor of Yellow Springs; served three terms as president of the medical staff at Springfield City Hospital; formerly medical superintendent of the District Tuberculosis Hospital; died January 1, aged 65, of coronary thrombosis.

August Herman Ringen, Sweet Springs, Mo.; Marion-Sims College of Medicine, St. Louis, 1899; member of the American Medical Association; died January 24, aged 76, of heart disease.

Clayton Elbert Royce, Tampa, Fla.; Columbia University College of Physicians and Surgeons, New York, 1911; member of the American Medical Association, American College of Physicians and the American Society of Clinical Pathologists; specialist certified by the American Board of Pathology; served on the staff of St. Vincent's Hospital in Jacksonville; died February 12, aged 60, of coronary occlusion.

John Hollibaugh Sanford, Santa Rosa, N. M.; University of Tennessee College of Medicine, Memphis, 1913; formerly mayor; died February 22, aged 56, of heart disease.

Kalmen Charles Sapero, Denver; Louisville (Ky.) Medical College, 1894; died February 28, aged 79, of cerebral hemorrhage.

Joseph J. Schultis ⊕ Butler, Pa.; Medico-Chirurgical College of Philadelphia, 1895; died recently, aged 75, of cardiac failure.

William Samuel Scott, Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1916; served during World War I; killed March 6, aged 52, when struck by an automobile.

David A. Sherrill, Newbern, Tenn.; University of Tennessee Medical Department, Nashville, 1888; died February 28, aged 89, of myocarditis and arteriosclerosis.

John Beach Solley ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1898; member of the American Psychoanalytic Association; for many years associated with the Manhattan Eye, Ear and Throat Hospital; died in St. Luke's Hospital March 3, aged 75, of cerebral hemorrhage.

Kuno Herbert Struck ⊕ Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1906; vice president of the Davenport Bank & Trust Company; served as secretary of the park board of Davenport, president of the library board, secretary of the Municipal Art Gallery board of trustees and president of the chamber of commerce; past president of the Scott County Medical Society; secretary and medical officer of a local draft board during World War I; died March 4, aged 63, of cerebral hemorrhage.

Clara Josephine Swan, Chardon, Ohio; State University of Iowa College of Homeopathic Medicine, Iowa City, 1887; member of the American Medical Association; died in the Huron Road Hospital, East Cleveland, March 7, aged 80, of carcinoma of the pancreas, with metastases.

Frank Lehr Thomas, Marion, Ohio; Eclectic Medical College, Cincinnati, 1924; member of the American Medical Association; served during World War I; member of the city school board; on the staff of the Marion City Hospital; died February 4, aged 54, of coronary thrombosis.

Edward F. Wehner, Clarksburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1902; honorary member of the Harrison County Medical Society and the West Virginia State Medical Association; fellow of the American College of Surgeons; on the staff of St. Mary's Hospital; died March 3, aged 71, of coronary thrombosis.

Benjamin Franklin White Jr., ⊕ Bradford, Pa.; Hahnemann Medical College and Hospital, Philadelphia, 1907; served overseas during World War I; on the staff of the Bradford Hospital; died February 7, aged 65, of arthritis.

Ruffin Ashe Wright, Mobile, Ala.; University of Virginia Department of Medicine, Charlottesville, 1889; member of the American Medical Association; died March 3, aged 81, of heart disease and pneumonia.

DIED WHILE IN MILITARY SERVICE

Thomas Matthew Calladine, Chicago; University of Rochester School of Medicine and Dentistry 1943; interned at the University of Chicago Clinics; began active duty as a lieutenant (jg) in the medical corps of the U. S. N. R., on Jan. 10, 1944; promoted to lieutenant; died in the Robert Merritt Billings Hospital February 27, aged 29, of testicular embryonal carcinoma with metastases.

William Stewart Chadwick, Beaufort, N. C.; Medical College of Virginia, Richmond, 1928; interned at the James Walker Memorial Hospital in Wilmington; formerly acting assistant surgeon in the U. S. Public Health Service; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve; promoted to commander; died in the Morehead City Hospital, Morehead City, Jan. 6, 1946, aged 43, of coronary thrombosis.

Frederick Ernest Keane Clarke, Santa Monica, Calif.; University and Bellevue Hospital Medical College, New York, 1927; member of the American Medical Association; diplomate of the National Board of Medical Examiners; interned at the Staten Island Hospital in Staten Island, N. Y.; formerly assistant in clinical medicine at his alma mater; served on the staffs of the Veterans Administration Facility in West Los Angeles and the Santa Monica Hospital; entered the medical corps, Army of the United States, as a captain on May 15, 1944; served in the Pacific theater with the 49th General Hospital; died while on terminal leave May 14, 1946, aged 47, of coronary occlusion.

Dual Alastair Macintyre, Palmer, N. Y.; Albany (N. Y.) Medical College, 1939; interned at the Meadowbrook Hospital in Hempstead, where he served a residency in surgery; diplomate of the National Board of Medical Examiners; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on May 25, 1942; promoted to lieutenant; drowned May 18, 1944, aged 32.

Roger Beasley Martin, New Rochelle, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1943; diplomate of the National Board of Medical Examiners; interned at the Johns Hopkins Hospital in Baltimore; captain, medical corps, Army of the United States; died in the Valley Forge General Hospital, Phoenixville, Pa., May 15, 1946, aged 30.

Charles Howard Mortimer ⊕ New York City; Columbia University College of Physicians and Surgeons, New York, 1937; served a residency at the Pilgrim State Hospital in Brentwood; formerly an intern at St. Vincent's Hospital in New York, where he served a residency; first lieutenant, medical corps, Army of the United States; passenger aboard B-24 aircraft which failed to return from combat ferry mission in 1944; presumptive date of death Jan. 26, 1946, aged 34, according to the U. S. Army.

Julius Hurst Smith ⊕ Lieutenant Commander (MC), U. S. Navy, Pelham, Ga.; University of Georgia School of Medicine, Augusta, 1941; interned at the Macon Hospital in Macon, Ga.; began active duty as lieutenant (jg) in the medical corps of the U. S. Naval Reserve in 1942; later joined the medical corps of the regular navy in the same rank; promoted to lieutenant and lieutenant commander; died in the Naval Hospital, San Diego, March 21, 1946, aged 31, of hepatic abscess.

Michael Thomas Tedesco, Hammond, Ind.; Eclectic Medical College, Cincinnati, 1928; interned at the Jennie Edmundson Memorial Hospital, Council Bluffs, Iowa; served a residency at the Lord Lister Hospital in Omaha; major, medical corps, Army of the United States; died in Camp Hood, Texas, April 16, 1945, aged 46, of general peritonitis secondary to appendical abscess.

Clarence Warren Whittaker, Easton, Maine; Tufts College Medical School, Boston, 1943; interned at the Boston City Hospital; diplomate of the National Board of Medical Examiners; began active duty as a first lieutenant in the medical corps, Army of the United States, in September 1944; promoted to captain; head of the medical department for a prisoner of war camp at Luzon Island in the Philippines; died in Luzon Island Sept. 20, 1946, aged 27, of pneumonia and injuries received in a jeep accident.

Penicillin in Suppurative Conditions of the Brain

At the Royal Society of Medicine a joint meeting of the Section of Neurology with the Société de neurologie of Paris was held. Sir Hugh Cairns discussed the use of penicillin in suppurative conditions of the brain and meninges. It might be given by the lumbar or cisternal route or into the lateral ventricle. Unless there was blockage it would spread freely. Normally 12,000 units would maintain a bacteriostatic level for twenty-four hours, but occasionally, for example early in pyogenic meningitis, this dose might have to be given every twelve hours. The upper limit of tolerance for crystalline penicillin had not been worked out; but heavy doses of 50,000 to 100,000 units might cause severe meningeal reactions. Such large doses could do no good and might do harm. There was never need to exceed 20,000 units in one day. Intrathecal penicillin continued for some weeks caused depression of the ankle jerks, suggesting damage to the cauda equina, which was reversible. Normally penicillin was given by the lumbar route. If there was a block, of which the most important sign was difficulty in obtaining cerebrospinal fluid by lumbar puncture, the cisternal route might be adopted. But with some head retraction this might not be easy, and blocks sometimes occurred above the cisterna magna, so that there should be no hesitation in injecting the lateral ventricle. For pachymeningitis and subdural abscess, penicillin was given into the subdural spaces, from which it passed about as rapidly as from muscle. Usually 8,000 to 10,000 units was injected every four hours.

Penicillin injected systemically did not pass in appreciable amounts into the cerebrospinal fluid. Nevertheless it had its value in pyogenic meningitis. It helped to combat the primary focus and the septicemia from the primary focus or a relapsing meningitis. It helped to overcome infection of the cerebral blood vessels. Probably penicillin could pass from the blood stream into the perivascular spaces of the brain and thus might be valuable in acute pyogenic meningitis (which is more correctly a meningoencephalitis). Also it might limit the spread of a brain abscess. Penicillin appeared to pass freely from the blood stream into the subdural space. Crystalline penicillin appeared to be nontoxic when given systemically. One patient received 300 million units without reaction. The sulfonamides should be given with penicillin; they were especially valuable when intrathecal penicillin was stopped. Until the diagnosis of meningitis was established bacteriologic treatment should be confined to systemic penicillin and sulfonamides.

S. Monckton Copeman: An Authority on Vaccination

Dr. S. Monckton Copeman, who at one time was the leading authority on vaccination, has died at the age of 85. In 1891 he became a medical officer to the Local Government Board. His papers on the relation between variola and vaccinia were so important that they were published in the *Proceedings of the Royal Society,* which awarded him its fellowship, the highest scientific distinction in this country. He is best known for his work on glycerinated lymph for vaccination. This device was not new, but he was the first to show the selective effect of the glycerin in eliminating extraneous germs from vaccine lymph without affecting the specific virus. One of the stock objections to Jenner's vaccination was that Jenner had never proved that there was any biologic relationship between cowpox and smallpox, so that it was absurd to think that an attack of one disease would produce immunity against a different disease. The results of inoculating calves with smallpox matter had not always been satisfactory. It occurred to Copeman to pass smallpox virus through monkeys and then to vaccinate a calf from a monkey. He thus produced typical vaccinia, which gave excellent strains of vaccine lymph. Copeman's view was that cowpox may have originated from inoculated smallpox. Although the inoculated strains rarely produced a general eruption, the local sore often itched badly. Copeman therefore suggested that it would be easy for the inoculated milker who scratched his arm to convey material to the udder.

The School Children of Copenhagen During the War

In October 1941 the senior school medical officer of Copenhagen, Dr. G. Jørgensen, sounded a note of warning about the health of school children under war conditions in Copenhagen. Measures were accordingly taken to counteract these conditions as much as possible, and from the beginning of 1943 a special ration of cod liver oil was issued, with the result that 87 per cent of the school children examined received some cod liver oil every day. At the same time an educational campaign for the better utilization of available food was conducted vigorously. A recent postwar survey of the health of the school children in Copenhagen by Dr. Knud Bojlen makes good reading; there has been no material deterioration in general health, and that telltale public health index, the tuberculin test, shows that the percentage of positive reactors declined steadily throughout the war.

Bovine Tuberculosis and BCG Vaccination

In 1937 tuberculosis had been stamped out in barely half the herds of cattle in Denmark. But the systematic campaign against this scourge has been so effective that by 1946 the claim could be made that between 95 and 100 per cent of the Danish herds were tuberculosis free. This means that fewer and fewer Danish children and adolescents will be tuberculin positive, and already there are several Danish schools in which practically all the students are tuberculin negative. Now that there is a prospect of systematic BCG vaccination of tuberculin negative persons at the school leaving age, it will be seen how comprehensive this measure will soon become. Already in the island of Bornholm over 22 per cent of all the inhabitants had undergone BCG vaccination by 1945, and it looks as if the pace set by Bornholm will be emulated by several other communities in Denmark.

Hay Fever

The incidence of hay fever depends on geography. In the five year period 1941-1945 Dr. E. Bruun and Dr. M. Schwartz treated 69 hay fever patients at the Rigshospital's polyclinic for cases of allergic disease. As many as 63 of these patients suffered from midsummer hay fever (June-July) while there were only 2 cases of spring hay fever (March-May) and only 4 cases of autumn hay fever (August-October). In the United States it seems that the autumn cases are the most numerous, a phenomenon reflecting differences in the flora of the two countries. In 67 cases desensitization was attempted by injections of an extract of pollen, good results being achieved in 59. These injections were as a rule started about April 1 and continued for two months, during which from twenty-four to thirty were given. Among the patients were 16 who also suffered from seasonal asthma, which in 14 cases disappeared completely under this prophylactic treatment.

Correspondence

PROPYLTHIOURACIL IN THYROTOXICOSIS

To the Editor:—The article on the use of propylthiouracil in thyrotoxicosis by Dr. William S. Reveno (The Journal, April 19, p. 1190) presented some unusual if not distressing data. Of 18 previously untreated cases, 9 were reported with initial basal metabolic rates ranging from plus 9 to plus 15 inclusive. While I am not unaware that thyrotoxicosis may occur with a metabolic rate near plus 15, such an occurrence is decidedly uncommon and should be supported by carefully documented observations. I believe the use of so potent and revolutionary a drug as propylthiouracil certainly demands more care in the selection of cases to be reported

Joseph S. Feibush, M.D., New York.

[Note.—This letter was referred to Dr. Reveno, who replies:]

To the Editor:—All the reported cases, including those with relatively low basal metabolic rates, presented a majority of the symptoms of thyrotoxicosis such as palpitation, nervousness, sweating, heat intolerance, weakness, weight loss, tremor, warm moist palms, lidlag or widened palpebral fissures and elevated pulse pressures. The thyroid gland showed either a nodular or a diffuse enlargement. Two initial basal metabolic rate determinations were made on separate days and the lower of these was reported. With the exception of 1 patient who died, all have since responded to treatment with subsidence of symptoms and lowering of the basal metabolic rate.

That 9 patients out of a small group showed basal metabolic rates under plus 15 per cent is not as important as that all presented unmistakable evidence of thyrotoxicosis.

William S. Reveno, M.D., Detroit.

COLD PACKS TO PROTECT TESTES IN MUMPS

To the Editor:—I read with interest a communication on cold packs suggested as a protective for testes in mumps in The Journal, Oct. 26, 1946. In view of the actual experience, it would be unfair to let the suggestion pass uncriticized. I am not a research scholar, nor am I given to "armchair philosophizing." With the large amount of clinical material available in India, I wish to record some observations which may have a bearing on the point at issue. I have seen patients with continuous high temperature (104-105 F.) for days on end without their productivity being affected in any way after the severe illness.

In India as a result of hot climate there is often a laxity of scrotal tissues. To prevent the unpleasant sensation of "drooping" testes in the loose scrotal bag it is customary in the working classes to keep them tightly held up by a double layer of a thick broad piece of cloth between the thighs and tied round the waist. This will be expected to raise the temperature of the testes to that of the body, particularly during hard physical exertion. After years of such habit, the persons are found to be as much potent for reproduction as before.

Thus it appears that rise of temperature does not appear to be the sole cause of degeneration of the testicular tissue in living subjects. In mumps the frequent involvement of testes and ovaries suggests that the causative virus is gonadotropic. It has a tendency to incite inflammatory changes in the gonads, which are often followed by fibrosis and atrophy. Under these circumstances it is extremely doubtful that cold packs will act as protective for testes in mumps, as suggested in the communication.

In practice I have found early multiple acupunctures of the tunica albuginea a useful procedure in the prevention of testicular atrophy in mumps. The procedure was first advocated by Henry Smith in 1864 for acute gonococcic epididymitis and later recommended for acute orchitis in mumps by Wesselhoeft and Vose (*New England J. Med.* **227**:277 [Aug. 20] 1942; cited in Operation for the Orchitis of Mumps, *Brit. M. J.* **1**:138 [Jan. 30] 1943). It is believed that tubular degeneration in mumps is brought about by increased intratesticular tension resulting from an acute inflammatory condition produced in it by the virus. Early acupuncture helps to relieve tension and thus prevents degeneration and atrophy of the testicular tissue. The authors mentioned recommend exposure of the swollen organ and a longitudinal or crucial incision of the tunica albuginea. The operation, they claim, affords an immediate relief of pain. They report 9 cases of orchitis in mumps in which they were able to prevent atrophy by early operative intervention. In practice in India, where such an elaborate operation cannot be undertaken, multiple acupunctures work as well.

Poona City, India.

AMERICAN ACADEMY FOR CEREBRAL PALSY

To the Editor:—I believe that the readers of The Journal will be particularly interested in an action which was taken in the latter part of January by a group of medical men who serve the National Society for Crippled Children and Adults as a medical advisory council in its national cerebral palsy program. The advisory council is composed of Dr. Earl Carlson of Long Island, N. Y., and Pompano, Fla., Dr. Bronson Crothers of Boston, Dr. George Deaver of New York, Dr. Temple Fay of Philadelphia, Dr. Meyer Perlstein of Chicago and Dr. Winthrop M. Phelps of Baltimore as chairman.

Meeting in Chicago at the time of the American Academy of Orthopedic Surgeons, this group voted to organize an American Academy for Cerebral Palsy, of which those present would constitute the charter members. Dr. Winthrop Phelps was selected as chairman and I was chosen secretary.

This action was taken because there is currently a tremendous interest in the cerebral palsied and a demand for services which are nonexistent. Trained personnel is desperately needed, and at present there are no standards for the training of such personnel.

In the opinion of the group the American Academy for Cerebral Palsy, though not serving as a certifying board, will set up certain standards of training, will serve as a clearing house for information and will be a focal point for interest in the field.

M. A. Perlstein, M.D., Chicago.

OTOSCLEROSIS

To the Editor:—In The Journal of March 29 I find an editorial regarding otosclerosis. Mention is not made of the use of benzyl cinnamate, otherwise known as Jacobson's Solution and distributed by E. Fougera & Co., New York. A preliminary report of the use of this solution was abstracted in The Journal, Dec. 25, 1943, page 1141. Since that time I have used this medication a number of times, the ages of the patients ranging from 25 to 75, and the results have been most gratifying both to the patients and to myself.

By the use of a balanced tuning fork I determine whether the eighth nerve is at fault; if it is I do not recommend benzyl cinnamate. In cases of conduction deafness, tinnitus and associated vertigo, relief has been gratifying and patients have been greatly helped.

John J. Smith, M.D., Santa Monica, Calif.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Revocation of License for Associating with Laymen.—The Dental Practice Act of West Virginia authorizes the revocation of a dentist's license for, among other things: ". . . professional connection or association with, or lending his name to another, for the illegal practice of dentistry, or professional connection or association with any person, firm or corporation, holding himself, themselves, or itself out in any manner contrary to this article." For a violation of this provision, the State Board of Dental Examiners revoked the defendant's license and from an order of the Circuit Court reversing this revocation order the petitioner, Huntington Dental Society, appealed to the Supreme Court of Appeals of West Virginia.

Prior to December 1943 one Harry Devore, a dental technician, had had his laboratory on Madison Avenue in Huntington, W. Va., adjoining the offices of Dr. Nichols, a practicing dentist. In 1942 five indictments were returned against Devore for the illegal practice of dentistry. He pleaded guilty to each count, was sentenced, served his time and then returned to his old office. Dr. Nichols died sometime before December 1943 and the defendant Winton, whose office was then on Third Avenue, decided that he would move to the office Nichols had occupied, at the same time retaining his office on Third Avenue in order to keep from losing practice until he became permanently located. In 1944 Devore was again indicted, and defendant was questioned by the Huntington Dental Society concerning his association with him. He gave up his Madison Avenue office and practiced only at his Third Avenue location until after Devore's acquittal, Dr. Winton having been one of Devore's principal witnesses. After Devore's acquittal he "started coming" to defendant's Third Avenue office, "picking up" impressions or molds and taking them to his Madison Avenue laboratory for prosthetic work, or the making of artificial teeth mounted on plates. About this time defendant consulted an attorney for the purpose of determining whether or not there was any reason why he should not occupy joint offices with Devore in the light of the fact that Devore had been indicted for the illegal practice of dentistry but acquitted. He was told that there was not. He therefore rented six rooms at the corner of Eighth Street and Sixth Avenue, three of which he occupied himself and three of which he sublet to Devore.

In September 1944 a professional investigator employed by the petitioner called Dr. Winton's office on the telephone, asked for an appointment and was told to come immediately. He went, found Devore at the office and recognized him as probably being the person with whom he had talked on the telephone. Being told that he wanted an upper and a lower plate, Devore seated him in a dental chair and stated that he must call Dr. Winton on the telephone. With whomever he talked he asked "Do you want me to go ahead and work on him?" The investigator did not hear the reply but states that Devore said that he would go ahead and "work on him." Devore then examined his mouth in detail, mixed a mortar or plaster to be used in taking an impression, placed a ladle containing the mixture in investigator's mouth, made an impression and went into his laboratory. Later he made an additional impression, being dissatisfied with the first. After Devore made the second impression, he stated that he had finished and asked for and received a $5 deposit, giving investigator a receipt for the deposit signed "Dr. J. L. Winton by H. C. D." (investigator using the name of K. E. Taylor) and telling him to return the following evening. As Devore was preparing the receipt defendant entered the office but neither investigator nor defendant spoke to each other. On September 28 investigator returned to the office and met Dr. Winton. Being informed that he wished to see the "Doctor" who had taken his impression Tuesday evening, defendant called to "Harry" and Devore appeared, placed investigator in the dental chair and proceeded to fit the two plates, returning to the laboratory to grind them two or three times. As investigator was leaving, Devore explained that he was not permitted to make impressions or to fit teeth and that defendant "fronted" for him. At the hearing, Dr. Winton's version of the conversation over the telephone was a direct contradiction to investigator's. Defendant said that Devore told him that there was a patient in the office who wished some impressions made and that his response was "Hold him. I will be there in a few minutes." It doesn't appear how long it took Devore to take the impressions or how long it took defendant to get from his home to his office. At any rate the impressions were evidently made in what defendant would estimate as "a few minutes," because when he reached his office they were finished. He said that he was very much incensed at Devore's having done the work, that he did not speak to Devore about it that evening but that the next morning he reprimanded him severely.

The surrounding circumstances, said the court, we regard as quite damaging to Dr. Winton's defense. Devore had been sentenced and convicted of violating the law by practicing dentistry illegally and had served time therefor. He had been indicted again for the same offense, tried and acquitted. It is fairly well established that, following his acquittal, he was illegally practicing dentistry in what were his and defendant's joint office. Defendant had had his attention directed to the questionableness of Devore's methods while the second indictment against Devore was pending and had then severed the connection. After that the association was renewed, however. Dr. Winton denies actual knowledge of many of these circumstances, particularly of the conviction of Devore, until after the second indictment. These are matters that casual inquiry would have disclosed. In a prior West Virginia case it was held that the decision of the Public Health Council (in the same situation as the Board of Dental Examiners in this case) revoking a license will not be disturbed on appeal unless the Council has exceeded its power or based its decision on a mistake of law. We believe, said the court, that it is necessary to find that the State Board of Dental Examiners attached more importance to the testimony of the witnesses of the petitioner than to that of Dr. Winton. In doing so it did not exceed its powers or commit a mistake of law. Accordingly the Supreme Court of Appeals reversed the order of the circuit court and directed that the revocation order of the State Board of Dental Examiners be reinstated.—*Huntington Dental Society v. Winton, 40 S. E. (2d) 769 (W. Va., 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, May 31, page 480.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Various centers, June 16-18. *Part III.* Various centers, June. Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: Part II. *Oral.* Cleveland, Oct. 5-11. Sec., Dr. P. [illegible] New York 24.

AMERICAN BOARD O[illegible], June 15-19. Chicago, October 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Part II. Chicago, *Jan. 22-23. Final date for filing applications is Sept. 15, 1947.* Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, [illegible] City, Ia.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

33:135-268 (Feb.) 1947
